## Example: Daily Asthma Presentations (1990:1993)

# Example: Pound-Dollar Exchange Rates (Oct 1, 1981 – Jun 28, 1985; Koopman website)

- Motivating Examples
  - Time series of counts
  - Stochastic volatility
- Generalized state-space models
  - Observation driven
  - Parameter driven
- Model setup and estimation
  - Estimation
    - ☞ Importance sampling
    - ☞ Approximation to the likelihood
- Simulation and Application
  - Time series of counts
  - Stochastic volatility
- How good is the posterior approximation?
  - Posterior mode vs posterior mean
- Application to estimating structural breaks
  - Poisson model
  - Stochastic volatility model

## Generalized State-Space Models

Observations:  $y^{(t)} = (y_1, \dots, y_t)$

States:  $\alpha^{(t)} = (\alpha_1, \dots, \alpha_t)$

Observation equation:

$$p(y_t | \alpha_t) := p(y_t | \alpha_t, \alpha^{(t-1)}, y^{(t-1)})$$

State equation:

-observation driven

$$p(\alpha_{t+1} | y^{(t)}) := p(\alpha_{t+1} | \alpha_t, \alpha^{(t-1)}, y^{(t)})$$

-parameter driven

$$p(\alpha_{t+1} | \alpha_t) := p(\alpha_{t+1} | \alpha_t, \alpha^{(t-1)}, y^{(t)})$$

## Exponential Family Setup for Parameter-Driven Model

Time series data:  $Y_1, \dots, Y_n$

Regression (explanatory) variable:  $\mathbf{x}_t$

Observation equation:

$$p(y_t | \alpha_t) = \exp\{(\alpha_t + \beta^T \mathbf{x}_t) y_t - b(\alpha_t + \beta^T \mathbf{x}_t) + c(y_t)\}.$$

State equation:  $\{\alpha_t\}$  follows an autoregressive process satisfying the recursions

$$\alpha_t = \gamma + \phi_1 \alpha_{t-1} + \phi_2 \alpha_{t-2} + \dots + \phi_p \alpha_{t-p} + \varepsilon_t,$$

where  $\{\varepsilon_t\} \sim \text{IID } N(0, \sigma^2)$ .

Note:  $\alpha_t = 0$  corresponds to standard generalized linear model.

Original primary objective: Inference about  $\beta$ .

## Examples of parameter driven models

### Poisson model for time series of counts

Observation equation:

$$p(y_t | \alpha_t) = \frac{e^{(\beta^T x_t + \alpha_t) y_t} e^{-e^{(\beta^T x_t + \alpha_t)}}}{y_t!}, \quad y_t = 0, 1, \dots,$$

State equation: State variables follow a Gaussian AR(1) process

$$\alpha_t = \phi \alpha_{t-1} + \varepsilon_t, \quad \{\varepsilon_t\} \sim \text{IID } N(0, \sigma^2)$$

The resulting transition density of the state variables is

$$p(\alpha_{t+1} | \alpha_t) = n(\alpha_{t+1}; \phi \alpha_t, \sigma^2)$$

Remark: The case  $\sigma^2 = 0$  corresponds to a log-linear model with Poisson noise.

## Examples of parameter driven models-cont

A stochastic volatility model for financial data (Taylor '86):

Model:

$$Y_t = \sigma_t Z_t, \{Z_t\} \sim \text{IID } N(0,1)$$

$$\alpha_t = \gamma + \phi \alpha_{t-1} + \varepsilon_t, \{\varepsilon_t\} \sim \text{IID } N(0, \sigma^2),$$

where  $\alpha_t = 2 \log \sigma_t$ .

The resulting observation and state transition densities are

$$p(y_t | \alpha_t) = n(y_t; 0, \exp(\alpha_t))$$

$$p(\alpha_{t+1} | \alpha_t) = n(\alpha_{t+1}; \gamma + \phi \alpha_t, \sigma^2)$$

Properties:

- Martingale difference sequence.
- Stationary.
- Strongly mixing at a geometric rate.

## Estimation Methods — Importance Sampling (Durbin and Koopman)

Model:

$$Y_t | \alpha_t, \mathbf{x}_t \sim \text{Pois}(\exp(\mathbf{x}_t^\top \beta + \alpha_t))$$

$$\alpha_t = \phi \alpha_{t-1} + \varepsilon_t, \quad \{\varepsilon_t\} \sim \text{IID } N(0, \sigma^2)$$

**Relative Likelihood:** Let  $\psi = (\beta, \phi, \sigma^2)$  and suppose  $g(y_n, \alpha_n; \psi_0)$  is an approximating joint density for  $Y_n = (Y_1, \dots, Y_n)'$  and  $\alpha_n = (\alpha_1, \dots, \alpha_n)'$ .

$$\begin{aligned} L(\psi) &= \int p(y_n | \alpha_n) p(\alpha_n) d\alpha_n \\ &= \int \frac{p(y_n | \alpha_n) p(\alpha_n)}{g(y_n, \alpha_n; \psi_0)} g(y_n, \alpha_n; \psi_0) d\alpha_n \\ &= \int \frac{p(y_n | \alpha_n) p(\alpha_n)}{g(y_n, \alpha_n; \psi_0)} g(\alpha_n | y_n; \psi_0) g(y_n; \psi_0) d\alpha_n \\ \frac{L(\psi)}{L_g(\psi_0)} &= \int \frac{p(y_n | \alpha_n) p(\alpha_n)}{g(y_n, \alpha_n; \psi_0)} g(\alpha_n | y_n; \psi_0) d\alpha_n \end{aligned}$$

## Importance Sampling (cont)

$$\begin{aligned}\frac{L(\psi)}{L_g(\psi_0)} &= \int \frac{p(y_n | \alpha_n) p(\alpha_n)}{g(y_n, \alpha_n; \psi_0)} g(\alpha_n | y_n; \psi_0) d\alpha_n \\ &= E_g \left[ \frac{p(y_n | \alpha_n) p(\alpha_n)}{g(y_n, \alpha_n; \psi_0)} \mid y_n; \psi_0 \right] \\ &\sim \frac{1}{N} \sum_{j=1}^N \frac{p(y_n | \alpha_n^{(j)}) p(\alpha_n^{(j)})}{g(y_n, \alpha_n^{(j)}; \psi_0)},\end{aligned}$$

where  $\{\alpha_n^{(j)}; j = 1, \dots, N\} \sim \text{iid } g(\alpha_n | y_n; \psi_0)$ .

### Notes:

- This is a “one-sample” approximation to the relative likelihood. That is, for one realization of the  $\alpha$ 's, we have, in principle, an approximation to the whole likelihood function.
- Approximation is only good in a neighborhood of  $\psi_0$ . Geyer suggests maximizing ratio wrt  $\psi$  and iterate replacing  $\psi_0$  with  $\hat{\psi}$ .

## Importance Sampling — example

Simulation example:  $Y_t | \alpha_t \sim \text{Pois}(\exp(.7 + \alpha_t))$ ,

$$\alpha_t = .5 \alpha_{t-1} + \varepsilon_t, \quad \{\varepsilon_t\} \sim \text{IID } N(0, .3), \quad n = 200, \quad N = 1000$$

# Importance Sampling — example

SV process:  $Y_t | \alpha_t \sim N(0, \exp\{\alpha_t\})$ ,

$$\alpha_t = -.368 + .95 \alpha_{t-1} + \varepsilon_t, \quad \{\varepsilon_t\} \sim \text{IID } N(0, .0676), \quad n = 200, \quad N = 1000$$

## Importance Sampling (cont)

Choice of *importance density*  $g$ :

Durbin and Koopman suggest a linear state-space approximating model

$$Y_t = \mu_t + \mathbf{x}_t^T \beta + \alpha_t + Z_t, \quad Z_t \sim N(0, H_t),$$

with

$$\mu_t = y_t - \hat{\alpha}_t - \mathbf{x}_t' y_t e^{-(\hat{\alpha}_t + \mathbf{x}_t' \beta)} + 1,$$

$$H_t = e^{-(\hat{\alpha}_t + \mathbf{x}_t' \beta)},$$

where the  $\hat{\alpha}_t = E_g(\alpha_t | y_n)$  are calculated recursively under the approximating model until convergence.

With this choice of approximating model, it turns out that

$$g(\alpha_n | y_n; \Psi_0) \sim N(\Gamma_n^{-1} \tilde{y}_n, \Gamma_n^{-1}),$$

where

$$\tilde{y}_n = y_n - e^{X\beta + \hat{\alpha}_n} + e^{X\beta + \hat{\alpha}_n} \hat{\alpha}_n,$$

$$\Gamma_n = \text{diag}(e^{X\beta + \hat{\alpha}_n}) + (E(\alpha_n \alpha_n'))^{-1}.$$

## Importance Sampling (cont)

Components required in the calculation.

- $g(y_n, \alpha_n)$ 
  - ◆  $\tilde{y}_n' \Gamma_n^{-1} \tilde{y}_n$
  - ◆  $\det(\Gamma_n)$
- simulate from  $N(\Gamma_n^{-1} \tilde{y}_n, \Gamma_n^{-1})$ 
  - ◆ compute  $\Gamma_n^{-1} \tilde{y}_n$
  - ◆ simulate from  $N(0, \Gamma_n^{-1})$

**Remark:** These quantities can be computed quickly using a version of the innovations algorithm or the Kalman smoothing recursions.

## Estimation Methods — Approximation to the likelihood

General setup:

$$p(y_n, \alpha_n) \propto p(y_n | \alpha_n) \det(G_n)^{1/2} \exp\{-(\alpha_n - \mu)^T G_n (\alpha_n - \mu) / 2\}$$

where

$$G_n^{-1} = E(\alpha_n - \mu)^T (\alpha_n - \mu)$$

Likelihood:

$$L(\psi) = \int p(y_n | \alpha_n) p(\alpha_n) d\alpha_n$$

Consider a Gaussian approximation  $p_a(\alpha_n | y_n) = \phi(\alpha_n; \mu_0, \Sigma_0)$  to the posterior

$$p(\alpha_n | y_n) \propto p(y_n | \alpha_n) p(\alpha_n)$$

Setting equal the respective posterior modes  $\alpha_a^*$  and  $\alpha^*$  of  $p_a(\alpha_n | y_n)$  and  $p(\alpha_n | y_n)$ , we have  $\mu_0 = \alpha^*$ , where  $\alpha^*$  is the solution of the equation

$$\frac{\partial}{\partial \alpha_n} \log p(y_n | \alpha_n, \psi) - G_n (\alpha_n - \mu) = 0$$

## Estimation Methods — Approximation to the likelihood (cont)

Matching Fisher information matrices:

$$\Sigma_0 = \left( -\frac{\partial^2}{\partial \alpha \partial \alpha^T} \log p(y_n | \alpha_n, \psi) \Big|_{\alpha_n = \alpha^*} + G_n \right)^{-1}$$

Approximating posterior:

$$p_a(\alpha_n | y_n, \psi) = \phi(\alpha_n, \alpha^*, \left( -\frac{\partial^2}{\partial \alpha \partial \alpha^T} \log p(y_n | \alpha_n, \psi) \Big|_{\alpha_n = \alpha^*} + G_n \right)^{-1})$$

Notes:

1. This approximating posterior is identical to the importance sampling density used by Durbin and Koopman.
2. In traditional Bayesian setting, posterior is approximately  $p_a$  for large  $n$  (see Bernardo and Smith, 1994).
3. Obtain same result if one applies a Taylor series expansion to the joint likelihood and ignore terms of order  $> 2$ .

## Estimation Methods — Approximation to the likelihood (cont)

Approximate likelihood: Note that

$$p(\alpha_n | y_n) = \frac{p(y_n | \alpha_n) p(\alpha_n)}{L(\psi; y_n)},$$

which by solving for L in the expression,

$$p_a(\alpha_n^* | y_n, \psi) = p(\alpha_n^* | y_n, \psi),$$

we obtain

$$\begin{aligned} L_a(\psi; y_n) &= p(y_n | \alpha^*, \psi) p(\alpha^*, \psi) / p_a(\alpha^* | y_n, \psi) \\ &= \frac{|G_n|^{1/2} p(y_n | \alpha^*, \psi) \exp\{-(\alpha^* - \mu)^T G_n (\alpha^* - \mu) / 2\}}{\det\left(-\frac{\partial^2}{\partial \alpha \partial \alpha^T} \log p(y_n | \alpha_n, \psi) \Big|_{\alpha^*} + G_n\right)^{1/2}} \end{aligned}$$

## Estimation Methods — Approximation to the likelihood (cont)

Case of exponential family:

$$L_a(\psi; \mathbf{y}_n) = \frac{|\mathbf{G}_n|^{1/2}}{(\mathbf{K} + \mathbf{G}_n)^{1/2}} \exp \{ \mathbf{y}_n^T \boldsymbol{\alpha}^* - 1^T \{ \mathbf{b}(\boldsymbol{\alpha}^*) - c(\mathbf{y}_n) \} - (\boldsymbol{\alpha}^* - \boldsymbol{\mu})^T \mathbf{G}_n (\boldsymbol{\alpha}^* - \boldsymbol{\mu}) / 2 \},$$

where

$$\mathbf{K} = \text{diag} \left\{ \left. \frac{\partial^2}{\partial \alpha_t^2} b_t(\alpha_t) \right|_{\alpha_t^*} \right\},$$

and  $\boldsymbol{\alpha}^*$  is the solution to the equation

$$\mathbf{y}_n - \frac{\partial}{\partial \boldsymbol{\alpha}_n} \mathbf{b}(\boldsymbol{\alpha}_n) - \mathbf{G}_n (\boldsymbol{\alpha}_n - \boldsymbol{\mu}) = 0.$$

Using a Taylor expansion, the latter equation can be solved iteratively.

## Estimation Methods — Approximation to the likelihood

Implementation:

1. Let  $\alpha^* = \alpha^*(\psi)$  be the converged value of  $\alpha^{(j)}(\psi)$ , where

$$\alpha^{(j+1)}(\psi) = (\ddot{\mathbf{b}}^j + G_n)^{-1} \tilde{\mathbf{y}}_n^j(\psi),$$

and

$$\tilde{\mathbf{y}}_n^j = \mathbf{y}_n - \dot{\mathbf{b}}^j + \ddot{\mathbf{b}}^j \alpha^{(j)} + G_n \boldsymbol{\mu}.$$

2. Maximize  $L_a(\psi; \mathbf{y}_n)$  with respect to  $\psi$ .

## Simulation Results

**Model:**  $Y_t | \alpha_t \sim \text{Pois}(\exp(.7 + \alpha_t))$ ,  $\alpha_t = .5 \alpha_{t-1} + \varepsilon_t$ ,  $\{\varepsilon_t\} \sim \text{IID } N(0, .3)$ ,  $n = 200$

## Application to Model Fitting for the Polio Data

Model for  $\{\alpha_t\}$ :

$$\alpha_t = \phi\alpha_{t-1} + \varepsilon_t, \quad \{\varepsilon_t\} \sim \text{IID } N(0, \sigma^2).$$

- Importance sampling (  $\psi_0$  updated 5 times for each  $N=100, 500, 1000,$  )
- Simulation based on 1000 replications and the fitted AL model.

## Application to Sydney Asthma Count Data

**Data:**  $Y_1, \dots, Y_{1461}$  daily asthma presentations in a Campbelltown hospital.

Preliminary analysis identified.

- no upward or downward trend
- **annual cycle** modeled by  $\cos(2\pi t/365), \sin(2\pi t/365)$
- **seasonal effect** modeled by

$$P_{ij}(t) = \frac{1}{B(2.5,5)} \left( \frac{t - T_{ij}}{100} \right)^{2.5} \left( 1 - \frac{t - T_{ij}}{100} \right)^5$$

where  $B(2.5,5)$  is the beta function and  $T_{ij}$  is the start of the  $j^{\text{th}}$  school term in year  $i$ .

- day of the week effect modeled by separate indicator variables for **Sunday** and **Monday** (increase in admittance on these days compared to Tues-Sat).
- Of the meteorological variables (max/min temp, humidity) and pollution variables (ozone, NO, NO<sub>2</sub>), only **humidity** at lags of 12-20 days and **NO<sub>2</sub>(max)** appear to have an association.

## Is the posterior distribution close to normal?

**Compare posterior mean with posterior mode:** Can compute the posterior mean using *SIR* (sampling importance-resampling) or particle filtering.

**Posterior mode:** The mode of  $p(\alpha_n | y_n)$  is  $\alpha^*$  found at the last iteration of AL.

**Posterior mean:** The mean of  $p(\alpha_n | y_n)$  can be found using SIR.

Let  $\alpha^{(1)}, \alpha^{(2)}, \dots, \alpha^{(N)}$  be independent draws from the multivariate distr  $p_a(\alpha_n | y_n)$ . For  $N$  large, an approximate iid sample from  $p(\alpha_n | y_n)$  can be obtained by drawing a random sample from  $\alpha^{(1)}, \alpha^{(2)}, \dots, \alpha^{(N)}$  with probabilities

$$p_i = \frac{w_i}{\sum_{i=1}^N w_i}, \quad w_i = \frac{p(\alpha^{(i)} | y_n)}{p_a(\alpha^{(i)} | y_n)} \propto \frac{L(\psi; y_n, \alpha^{(i)})}{p_a(\alpha^{(i)} | y_n)}, \quad i = 1, \dots, N.$$

## Posterior mean vs posterior mode?

Polio data: blue = mean, red = mode

## Posterior mean vs posterior mode?

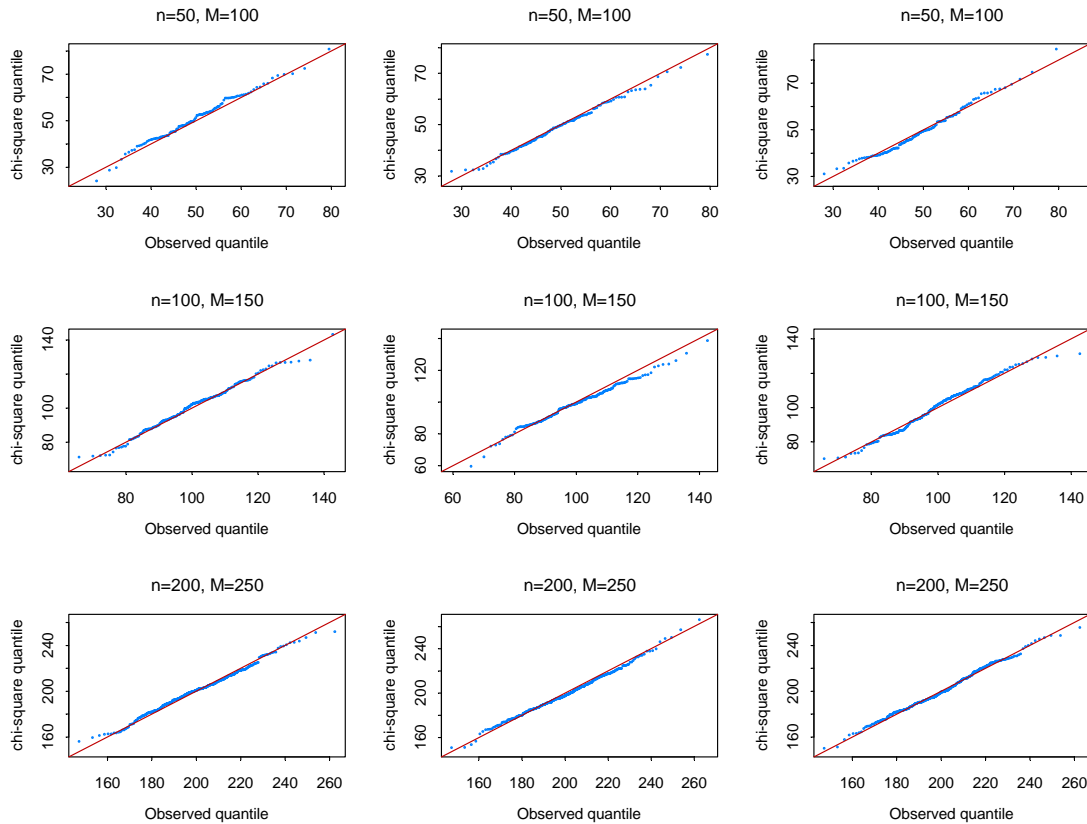

Pound/US exchange rate data: blue = mean, red = mode

## Is the posterior distribution close to normal?

Suppose  $\alpha^{(1)}, \alpha^{(2)}, \dots, \alpha^{(M)}$  are independent draws from the multivariate distr  $p(\alpha_n | y_n)$ , generated using SIR. Then

$$d_j^2 = (\alpha^{(j)} - \alpha^*)^T (K + G_n) (\alpha^{(j)} - \alpha^*) \stackrel{iid}{\sim} \chi_n^2$$

*Correlations are not significant.*

## Application to Structural Breaks (Davis, Lee, Rodriguez-Yam)

### State Space Model Setup:

#### Observation equation:

$$p(y_t | \alpha_t) = \exp\{\alpha_t y_t - b(\alpha_t) + c(y_t)\}.$$

#### State equation: $\{\alpha_t\}$ follows the piecewise AR(1) model given by

$$\alpha_t = \gamma_k + \phi_k \alpha_{t-1} + \sigma_k \varepsilon_t, \quad \text{if } \tau_{k-1} \leq t < \tau_k,$$

where  $1 = \tau_0 < \tau_1 < \dots < \tau_m < n$ , and  $\{\varepsilon_t\} \sim \text{IID } N(0,1)$ .

#### Parameters:

$m$  = number of break points

$\tau_k$  = location of break points

$\gamma_k$  = level in  $k^{\text{th}}$  epoch

$\phi_k$  = AR coefficients  $k^{\text{th}}$  epoch

$\sigma_k$  = scale in  $k^{\text{th}}$  epoch

## Application to Structural Breaks—(cont)

**Estimation:** For  $(m, \tau_1, \dots, \tau_m)$  fixed, calculate the approximate likelihood evaluated at the “MLE”, i.e.,

$$L_a(\hat{\psi}; y_n) = \frac{|G_n|^{1/2}}{(K + G_n)^{1/2}} \exp\{y_n^T \alpha^* - 1^T \{b(\alpha^*) - c(y_n)\} - (\alpha^* - \mu)^T G_n (\alpha^* - \mu) / 2\},$$

where  $\hat{\psi} = (\hat{\gamma}_1, \dots, \hat{\gamma}_m, \hat{\phi}_1, \dots, \hat{\phi}_m, \hat{\sigma}_1^2, \dots, \hat{\sigma}_m^2)$  is the MLE.

**Goal:** Optimize an *objective function* over  $(m, \tau_1, \dots, \tau_m)$ .

**Implementation problems:**

- choice of objective function?
- how to optimize over  $(m, \tau_1, \dots, \tau_m)$ ?

**Solutions(?):**

- use minimum description length (MDL) as an objective function
- use genetic algorithm for optimization

## Application to Structural Breaks—(cont)

**Minimum Description Length (MDL):** Choose the model which maximizes the compression of the data or, equivalently, select the model that minimizes the code length of the data (i.e., amount of memory required to store the data).

$$\begin{aligned} \text{Code Length("data")} &= \text{CL("fitted model")} + \text{CL("data | fitted model")} \\ &\sim \text{CL("parameters")} + \text{CL("residuals")} \end{aligned}$$

$$\begin{aligned} MDL(m, \tau_1, \dots, \tau_m) \\ &= \underbrace{\log(m) + m \log(n) + 1.5 \sum_{j=1}^m \log(\tau_j - \tau_{j-1})}_{CL(\text{"Parameters"})} - \underbrace{\sum_{j=1}^m \log(L_a(\hat{\psi}_j; y_{\tau_{j-1}:\tau_j}))}_{CL(\text{"residuals"})} \end{aligned}$$

**Generalization:** AR(p) segments can have unknown order.

$$\begin{aligned} MDL(m, (\tau_1, p_1), \dots, (\tau_m, p_m)) \\ &= \log(m) + m \log(n) + 0.5 \sum_{j=1}^m (p_j + 2) \log(\tau_j - \tau_{j-1}) - \sum_{j=1}^m \log(L_a(\hat{\psi}_j; y_{\tau_{j-1}:\tau_j})) \end{aligned}$$

## Application to Structural Breaks—(cont)

**Genetic Algorithm:** Chromosome consists of  $n$  genes, each taking the value of  $-1$  (no break) or  $p$  (order of AR process). Use natural selection to find a *near* optimal solution.

Map the break points with a chromosome  $c$  via

$$(m, (\tau_1, p_1), \dots, (\tau_m, p_m)) \longleftrightarrow c = (\delta_1, \dots, \delta_n),$$

Where

$$\delta_t = \begin{cases} -1, & \text{if no break point at } t, \\ p, & \text{if break point at time } t \text{ and AR order is } p. \end{cases}$$

For example,

$$c = (2, -1, -1, -1, -1, 0, -1, -1, -1, -1, 0, -1, -1, -1, -1, 3, -1, -1, -1, -1)$$

$t: 1$  $6$  $11$  $16$

would correspond to a process as follows:

$$\text{AR}(2), t=1:5; \text{AR}(0), t=6:10; \text{AR}(0), t=11:15; \text{AR}(3), t=16:20$$

## Implementation of Genetic Algorithm—(cont)

**Generation 0:** Start with  $L$  (200) randomly generated chromosomes,  $c_1, \dots, c_L$  with associated MDL values,  $M(c_1), \dots, M(c_L)$ .

**Generation 1:** A new child in the next generation is formed from the chromosomes  $c_1, \dots, c_L$  of the previous generation as follows:

- with probability  $\pi_c$ , *crossover* occurs.
  - two parent chromosomes  $c_i$  and  $c_j$  are selected at random with probabilities proportional to the ranks of  $M(c_i)$ .
  - $k^{\text{th}}$  gene of child is  $\delta_k = \delta_{i,k}$  w.p.  $1/2$  and  $\delta_{j,k}$  w.p.  $1/2$
- with probability  $1 - \pi_c$ , *mutation* occurs.
  - a parent chromosome  $c_i$  is selected
  - $k^{\text{th}}$  gene of child is  $\delta_k = \delta_{i,k}$  w.p.  $\pi_1$ ;  $-1$  w.p.  $\pi_2$ ; and  $p$  w.p.  $\alpha_p$

## Implementation of Genetic Algorithm—(cont)

Execution of GA: Run GA for numerous generations or until *convergence*.

Various Strategies:

- include the *top* ten chromosomes from past generations in future generations.
- use multiple *islands*, in which populations run independently, and then allow *migration* after a fixed number of generations.

## Count Data Example

**Model:**  $Y_t | \alpha_t \sim \text{Pois}(\exp\{\beta + \alpha_t\})$ ,  $\alpha_t = \phi\alpha_{t-1} + \varepsilon_t$ ,  $\{\varepsilon_t\} \sim \text{IID } N(0, \sigma^2)$

### True model:

- $Y_t | \alpha_t \sim \text{Pois}(\exp\{.7 + \alpha_t\})$ ,  $\alpha_t = .5\alpha_{t-1} + \varepsilon_t$ ,  $\{\varepsilon_t\} \sim \text{IID } N(0, .3)$ ,  $t < 250$
- $Y_t | \alpha_t \sim \text{Pois}(\exp\{.7 + \alpha_t\})$ ,  $\alpha_t = -.5\alpha_{t-1} + \varepsilon_t$ ,  $\{\varepsilon_t\} \sim \text{IID } N(0, .3)$ ,  $t > 250$ .
- GA estimate 251, time 267secs

## SV Process Example

**Model:**  $Y_t | \alpha_t \sim N(0, \exp\{\alpha_t\})$ ,  $\alpha_t = \gamma + \phi \alpha_{t-1} + \varepsilon_t$ ,  $\{\varepsilon_t\} \sim \text{IID } N(0, \sigma^2)$

### True model:

- $Y_t | \alpha_t \sim N(0, \exp\{\alpha_t\})$ ,  $\alpha_t = -.05 + .975\alpha_{t-1} + \varepsilon_t$ ,  $\{\varepsilon_t\} \sim \text{IID } N(0, .05)$ ,  $t < 1500$
- $Y_t | \alpha_t \sim N(0, \exp\{2\alpha_t\})$ ,  $\alpha_t = -.25 + .900\alpha_{t-1} + \varepsilon_t$ ,  $\{\varepsilon_t\} \sim \text{IID } N(0, .25)$ ,  $t > 1500$ .
- GA estimate 1502, time 1049secs

## SV Process Example

**Model:**  $Y_t | \alpha_t \sim N(0, \exp\{\alpha_t\})$ ,  $\alpha_t = \gamma + \phi \alpha_{t-1} + \varepsilon_t$ ,  $\{\varepsilon_t\} \sim \text{IID } N(0, \sigma^2)$

### True model:

- $Y_t | \alpha_t \sim N(0, \exp\{\alpha_t\})$ ,  $\alpha_t = -.175 + .977\alpha_{t-1} + \varepsilon_t$ ,  $\{\varepsilon_t\} \sim \text{IID } N(0, .1810)$ ,  $t < 251$
- $Y_t | \alpha_t \sim N(0, \exp\{\alpha_t\})$ ,  $\alpha_t = -.010 + .996\alpha_{t-1} + \varepsilon_t$ ,  $\{\varepsilon_t\} \sim \text{IID } N(0, .0089)$ ,  $t > 250$ .
- GA estimate 251, time 269s

## SV Process Example-(cont)

True model:

- $Y_t | \alpha_t \sim N(0, \exp\{\alpha_t\})$ ,  $\alpha_t = -.175 + .977\alpha_{t-1} + \varepsilon_t$ ,  $\{\varepsilon_t\} \sim \text{IID } N(0, .1810)$ ,  $t < 251$
- $Y_t | \alpha_t \sim N(0, \exp\{\alpha_t\})$ ,  $\alpha_t = -.010 + .996\alpha_{t-1} + \varepsilon_t$ ,  $\{\varepsilon_t\} \sim \text{IID } N(0, .0089)$ ,  $t > 250$ .

Fitted model based on no structural break:

- $Y_t | \alpha_t \sim N(0, \exp\{\alpha_t\})$ ,  $\alpha_t = -.0645 + .9889\alpha_{t-1} + \varepsilon_t$ ,  $\{\varepsilon_t\} \sim \text{IID } N(0, .0935)$

## Linear Process Example (Monthly Deaths & Serious Injuries, UK)

**Data:**  $Y_t$  = number of monthly deaths and serious injuries in UK, Jan '75 – Dec '84, ( $t = 1, \dots, 120$ )

**Remark:** Seat belt legislation introduced in Feb '83 ( $t = 99$ ).

## Linear Process Example (Monthly Deaths & Serious Injuries, UK)

**Data:**  $Y_t$  = number of monthly deaths and serious injuries in UK, Jan '75 – Dec '84, ( $t = 1, \dots, 120$ )

**Remark:** Seat belt legislation introduced in Feb '83 ( $t = 99$ ).

**Results from GA:** 3 pieces; time = 4.4secs

**Piece 1:** ( $t=1, \dots, 98$ ) IID; **Piece 2:** ( $t=99, \dots, 108$ ) IID; **Piece 3:**  $t=109, \dots, 120$  AR(1)

## Summary Remarks

1. Importance sampling offers a nice clean method for estimation in parameter driven models.
2. Relative likelihood approach is a one-sample based procedure, but may have convergence problems.
3. Approximation to the likelihood is a non-simulation based procedure which may have great potential especially with large sample sizes and/or large number of explanatory variables.
5. Approximate likelihood approach is amenable to bootstrapping procedures for bias correction.
6. Posterior mode matches posterior mean reasonably well.
7. Approximate likelihood approach may be useful to the problem of structural break detection.
