Outline

- ➡ Characteristics of some financial time series
 - IBM returns
 - Multiplicative models for log-returns (GARCH, SV)
- ➡ Regular variation
 - univariate case
 - multivariate case
 - new characterization: \mathbf{X} is RV $\Leftrightarrow \mathbf{c}'\mathbf{X}$ is RV ?
- ➡ Applications of regular variation
 - Stochastic recurrence equations (GARCH)
 - Point process convergence
 - Extremes and extremal index
 - Limit behavior of sample correlations
- ➡ Wrap-up

Characteristics of some financial time series

Define $X_t = \ln(P_t) - \ln(P_{t-1})$ (log returns)

- heavy tailed

$$P(|X_1| > x) \sim C x^{-\alpha}, \quad 0 < \alpha < 4.$$

- uncorrelated

$\hat{\rho}_x(h)$ near 0 for all lags $h > 0$ (MGD sequence)

- $|X_t|$ and X_t^2 have slowly decaying autocorrelations

$\hat{\rho}_{|X|}(h)$ and $\hat{\rho}_{X^2}(h)$ converge to 0 *slowly* as h increases.

- process exhibits 'volatility clustering'.

Log returns for IBM 1/3/62-11/3/00 (blue=1961-1981)

Sample ACF IBM (a) 1962-1981, (b) 1982-2000

(a) ACF of IBM (1st half)

(b) ACF of IBM (2nd half)

Sample ACF of abs values for IBM (a) 1961-1981, (b) 1982-2000

Hill's plot of tail index for IBM (1962-1981, 1982-2000)

Multiplicative models for log(returns)

Basic model

$$\begin{aligned} X_t &= \ln(P_t) - \ln(P_{t-1}) \quad (\text{log returns}) \\ &= \sigma_t Z_t, \end{aligned}$$

where

- $\{Z_t\}$ is IID with mean 0, variance 1 (if exists). (e.g. $N(0,1)$ or a t -distribution with ν df.)
- $\{\sigma_t\}$ is the volatility process
- σ_t and Z_t are independent.

Properties:

- $EX_t = 0$, $\text{Cov}(X_t, X_{t+h}) = 0$, $h > 0$ (uncorrelated if $\text{Var}(X_t) < \infty$)
- conditional heteroscedastic (condition on σ_t).

Multiplicative models for log(returns)-cont

$$X_t = \sigma_t Z_t \quad (\text{observation eqn in state-space formulation})$$

Two classes of models for volatility:

(i) GARCH(p,q) process (General AutoRegressive Conditional Heteroscedastic-observation-driven specification)

$$\sigma_t^2 = \alpha_0 + \alpha_1 X_{t-1}^2 + \dots + \alpha_p X_{t-p}^2 + \beta_1 \sigma_{t-1}^2 + \dots + \beta_q \sigma_{t-q}^2 .$$

Special case: ARCH(1):

$$\begin{aligned} X_t^2 &= (\alpha_0 + \alpha_1 X_{t-1}^2) Z_t^2 \\ &= \alpha_1 Z_t^2 X_{t-1}^2 + \alpha_0 Z_t^2 \\ &= A_t X_{t-1}^2 + B_t \end{aligned} \quad (\text{stochastic recurrence eqn})$$

$$\rho_{X^2}(h) = \alpha_1^h, \text{ if } \alpha_1^2 < 1/3.$$

Multiplicative models for log(returns)-cont

GARCH(2,1): $X_t = \sigma_t Z_t$, $\sigma_t^2 = \alpha_0 + \alpha_1 X_{t-1}^2 + \alpha_2 X_{t-2}^2 + \beta_1 \sigma_{t-1}^2$.

Then $\mathbf{Y}_t = (\sigma_t^2, X_{t-1}^2)'$ follows the SRE given by

$$\begin{bmatrix} \sigma_t^2 \\ X_{t-1}^2 \end{bmatrix} = \begin{bmatrix} \alpha_1 Z_{t-1}^2 + \beta_1 & \alpha_2 \\ Z_{t-1}^2 & 0 \end{bmatrix} \begin{bmatrix} \sigma_{t-1}^2 \\ X_{t-2}^2 \end{bmatrix} + \begin{bmatrix} \alpha_0 \\ 0 \end{bmatrix}$$

Questions:

- Existence of a unique stationary solution to the SRE?
- Regular variation of the joint distributions?

Multiplicative models for log(returns)-cont

$$X_t = \sigma_t Z_t \text{ (observation eqn in state-space formulation)}$$

(ii) stochastic volatility process (parameter-driven specification)

$$\log \sigma_t^2 = \sum_{j=-\infty}^{\infty} \psi_j \varepsilon_{t-j}, \quad \sum_{j=-\infty}^{\infty} \psi_j^2 < \infty, \quad \{\varepsilon_t\} \sim \text{IIDN}(0, \sigma^2)$$

$$\rho_{X^2}(h) = \text{Cor}(\sigma_t^2, \sigma_{t+h}^2) / EZ_1^4$$

Question:

- Joint distributions of process regularly varying if distr of Z_1 is regularly varying?

Regular variation — univariate case

Def: The random variable X is *regularly varying with index* α if

$$P(|X| > tx) / P(|X| > t) \rightarrow x^{-\alpha} \text{ and } P(X > t) / P(|X| > t) \rightarrow p,$$

or, equivalently, if

$$P(X > tx) / P(|X| > t) \rightarrow px^{-\alpha} \text{ and } P(X < -tx) / P(|X| > t) \rightarrow qx^{-\alpha},$$

where $0 \leq p \leq 1$ and $p+q=1$.

Equivalence:

X is $RV(\alpha)$ if and only if $P(X \in t \bullet) / P(|X| > t) \rightarrow_v \mu(\bullet)$

(\rightarrow_v vague convergence of measures on $\mathbb{R} \setminus \{0\}$). In this case,

$$\mu(dx) = \left(p\alpha x^{-\alpha-1} I(x>0) + q\alpha (-x)^{-\alpha-1} I(x<0) \right) dx$$

Note: $\mu(tA) = t^{-\alpha} \mu(A)$ for every t and A bounded away from 0.

Regular variation — univariate case (cont)

Another formulation (polar coordinates):

Define the ± 1 valued rv θ , $P(\theta = 1) = p$, $P(\theta = -1) = 1 - p = q$.

Then

X is $RV(\alpha)$ if and only if

$$\frac{P(|X| > t x, X/|X| \in S)}{P(|X| > t)} \rightarrow x^{-\alpha} P(\theta \in S)$$

or

$$\frac{P(|X| > t x, X/|X| \in \bullet)}{P(|X| > t)} \rightarrow_v x^{-\alpha} P(\theta \in \bullet)$$

(\rightarrow_v vague convergence of measures on $S^0 = \{-1, 1\}$).

Regular variation — multivariate case

Multivariate regular variation of $\mathbf{X}=(X_1, \dots, X_m)$: There exists a random vector $\theta \in \mathbf{S}^{m-1}$ such that

$$P(|\mathbf{X}| > t x, \mathbf{X}/|\mathbf{X}| \in \bullet) / P(|\mathbf{X}| > t) \rightarrow_v x^{-\alpha} P(\theta \in \bullet)$$

(\rightarrow_v vague convergence on \mathbf{S}^{m-1} , unit sphere in \mathbf{R}^m).

- $P(\theta \in \bullet)$ is called the **spectral measure**
- α is the **index of \mathbf{X}** .

Equivalence:

$$\frac{P(\mathbf{X} \in t\bullet)}{P(|\mathbf{X}| > t)} \rightarrow_v \mu(\bullet)$$

μ is a measure on \mathbf{R}^m which satisfies for $x > 0$ and A bounded away from 0,

$$\mu(xB) = x^{-\alpha} \mu(xA).$$

Regular variation — multivariate case (cont)

Examples:

1. If $X_1 > 0$ and $X_2 > 0$ are iid $\text{RV}(\alpha)$, then $\mathbf{X} = (X_1, X_2)$ is multivariate regularly varying with index α and *spectral distribution*

$$P(\theta = (0,1)) = P(\theta = (1,0)) = .5 \quad (\text{mass on axes}).$$

Interpretation: Unlikely that X_1 and X_2 are very large at the same time.

Figure: plot of (X_{t1}, X_{t2}) for realization of 10,000.

2. If $X_1 = X_2 > 0$, then $\mathbf{X} = (X_1, X_2)$ is multivariate regularly varying with index α and *spectral distribution*

$$P(\theta = (1/\sqrt{2}, 1/\sqrt{2})) = 1.$$

3. AR(1): $X_t = .9 X_{t-1} + Z_t$, $\{Z_t\} \sim \text{IID symmetric stable (1.8)}$

Distr of θ : $\begin{cases} \pm(1,.9)/\text{sqrt}(1.81), \text{ W.P. } .9898 \\ \pm(0,1), \\ \text{ W.P. } .0102 \end{cases}$

Figure: plot of (X_t, X_{t+1}) for realization of 10,000.

Applications of multivariate regular variation

- Domain of attraction for *sums of iid random vectors* (Rvaceva, 1962). That is, when does the partial sum

$$a_n^{-1} \sum_{t=1}^n \mathbf{X}_t$$

converge for some constants a_n ?

- *Spectral measure* of multivariate stable vectors.
- *Domain of attraction* for componentwise maxima of iid random vectors (Resnick, 1987). Limit behavior of

$$a_n^{-1} \bigvee_{t=1}^n \mathbf{X}_t$$

- Weak convergence of *point processes* with iid points.
- Solution to *stochastic recurrence equations*, $\mathbf{Y}_t = \mathbf{A}_t \mathbf{Y}_{t-1} + \mathbf{B}_t$
- Weak convergence of *sample autocovariances*.

Operations on regularly varying vectors — products

Products (Breiman 1965). Suppose $X, Y > 0$ are independent with $X \sim \text{RV}(\alpha)$ and $EY^{\alpha+\varepsilon} < \infty$ for some $\varepsilon > 0$. Then $XY \sim \text{RV}(\alpha)$ with

$$P(XY > x) \sim EY^\alpha P(X > x).$$

Multivariate version. Suppose the random vector \mathbf{X} is regularly varying and \mathbf{A} is a matrix independent of \mathbf{X} with

$$0 < E\|\mathbf{A}\|^{\alpha+\varepsilon} < \infty.$$

Then

$\mathbf{A}\mathbf{X}$ is regularly varying with index α .

Applications of multivariate regular variation (cont)

Linear combinations:

$\mathbf{X} \sim \text{RV}(\alpha) \Rightarrow$ all linear combinations of \mathbf{X} are regularly varying

i.e., there exist α and slowly varying fcn $L(\cdot)$, s.t.

$$P(\mathbf{c}^T \mathbf{X} > t) / (t^\alpha L(t)) \rightarrow w(\mathbf{c}), \text{ exists for all real-valued } \mathbf{c},$$

where

$$w(t\mathbf{c}) = t^{-\alpha} w(\mathbf{c}).$$

Use vague convergence with $A_{\mathbf{c}} = \{\mathbf{y} : \mathbf{c}^T \mathbf{y} > 1\}$, i.e.,

$$\frac{P(\mathbf{X} \in tA_{\mathbf{c}})}{t^{-\alpha} L(t)} = \frac{P(\mathbf{c}^T \mathbf{X} > t)}{P(|\mathbf{X}| > t)} \rightarrow \mu(A_{\mathbf{c}}) =: w(\mathbf{c}),$$

where $t^\alpha L(t) = P(|\mathbf{X}| > t)$.

Applications of multivariate regular variation (cont)

Converse?

$\mathbf{X} \sim \text{RV}(\alpha) \iff$ all linear combinations of \mathbf{X} are regularly varying?

There exist α and slowly varying fcn $L(\cdot)$, s.t.

(LC) $P(\mathbf{c}^T \mathbf{X} > t) / (t^\alpha L(t)) \rightarrow w(\mathbf{c})$, exists for all real-valued \mathbf{c} .

Theorem (Basrak, Davis, Mikosch, '02). Let \mathbf{X} be a random vector.

1. If \mathbf{X} satisfies (LC) with α non-integer, then \mathbf{X} is $\text{RV}(\alpha)$.
2. If $\mathbf{X} > 0$ satisfies (LC) for non-negative \mathbf{c} and α is non-integer, then \mathbf{X} is $\text{RV}(\alpha)$.
3. If $\mathbf{X} > 0$ satisfies (LC) with α an odd integer, then \mathbf{X} is $\text{RV}(\alpha)$.

Applications of multivariate regular variation (cont)

Idea of argument: Define the measures

$$m_t(\bullet) = P(\mathbf{X} \in t\bullet) / (t^\alpha L(t))$$

- By assumption we know that for fixed \mathbf{c} , $m_t(A_{\mathbf{c}}) \rightarrow \mu(A_{\mathbf{c}})$.
- $\{m_t\}$ is tight: For B bded away from 0, $\sup_t m_t(B) < \infty$.
- Do subsequential limits of $\{m_t\}$ coincide?

If $m_{t'} \rightarrow_v \mu_1$ and $m_{t''} \rightarrow_v \mu_2$, then

$$\mu_1(A_{\mathbf{c}}) = \mu_2(A_{\mathbf{c}}) \text{ for all } \mathbf{c} \neq \mathbf{0}.$$

Problem: Need $\mu_1 = \mu_2$ but only have equality on $A_{\mathbf{c}}$, not a π -system.

In general, equality need not hold (see Ex 6.1.35 in Meerschaert & Scheffler (2001)).

Applications of theorem

1. **Kesten (1973)**. Under general conditions, **(LC)** holds with $L(t)=1$ for stochastic recurrence equations of the form

$$\mathbf{Y}_t = \mathbf{A}_t \mathbf{Y}_{t-1} + \mathbf{B}_t, \quad (\mathbf{A}_t, \mathbf{B}_t) \sim \text{IID},$$

\mathbf{A}_t $d \times d$ random matrices, \mathbf{B}_t random d -vectors.

It follows that the distributions of \mathbf{Y}_t , and in fact all of the finite dim'l distrs of \mathbf{Y}_t are regularly varying (if α is non-even).

2. **GARCH processes**. Since squares of a GARCH process can be embedded in a SRE, the *finite dimensional distributions* of a **GARCH** are regularly varying.

Examples

Example of ARCH(1): $X_t = (\alpha_0 + \alpha_1 X_{t-1}^2)^{1/2} Z_t$, $\{Z_t\} \sim \text{IID}$.

α found by solving $E|\alpha_1 Z^2|^{\alpha/2} = 1$.

α_1	.312	.577	1.00	1.57
α	8.00	4.00	2.00	1.00

Distr of θ :

$$P(\theta \in \bullet) = E\{ \|(B,Z)\|^\alpha I(\arg((B,Z)) \in \bullet) \} / E\|(B,Z)\|^\alpha$$

where

$$P(B = 1) = P(B = -1) = .5$$

Examples (cont)

Example of ARCH(1): $\alpha_0=1, \alpha_1=1, \alpha=2, X_t=(\alpha_0+\alpha_1 X_{t-1}^2)^{1/2}Z_t, \{Z_t\}\sim\text{IID}$

Figures: plots of (X_t, X_{t+1}) and estimated distribution of θ for realization of 10,000.

Applications of theorem (cont)

Example: SV model $X_t = \sigma_t Z_t$

Suppose $Z_t \sim \text{RV}(\alpha)$ and

$$\log \sigma_t^2 = \sum_{j=-\infty}^{\infty} \psi_j \varepsilon_{t-j}, \quad \sum_{j=-\infty}^{\infty} \psi_j^2 < \infty, \quad \{\varepsilon_t\} \sim \text{IIDN}(0, \sigma^2).$$

Then $\mathbf{Z}_n = (Z_1, \dots, Z_n)'$ is regular varying with index α and so is

$$\mathbf{X}_n = (X_1, \dots, X_n)' = \text{diag}(\sigma_1, \dots, \sigma_n) \mathbf{Z}_n$$

with spectral distribution concentrated on $(\pm 1, 0), (0, \pm 1)$.

Figure: plot of
 (X_t, X_{t+1}) for
realization of 10,000.

Point process application

Theorem Let $\{\mathbf{X}_t\}$ be an iid sequence of random vectors satisfying 1 of the 3 conditions in the theorem. Then

$$N_n := \sum_{t=1}^n \varepsilon_{\mathbf{X}_t/a_n} \xrightarrow{d} N := \sum_{j=1}^{\infty} \varepsilon_{P_j \boldsymbol{\theta}_j},$$

if and only if for every $\mathbf{c} \neq \mathbf{0}$

$$N_{n,\mathbf{c}} := \sum_{t=1}^n \varepsilon_{\mathbf{c}'\mathbf{X}_t/a_n} \xrightarrow{d} N_{\mathbf{c}} := \sum_{j=1}^{\infty} \varepsilon_{\mathbf{c}'P_j \boldsymbol{\theta}_j},$$

where $\{a_n\}$ satisfies $nP(|\mathbf{X}_t| > a_n) \rightarrow 1$, and N is a Poisson process with intensity measure μ .

- $\{P_j\}$ are Poisson pts corresponding to the radial part, i.e., has intensity measure $\propto x^{-\alpha-1} (dx)$.
- $\{\boldsymbol{\theta}_j\}$ are iid with the spectral distribution given by the RV

Point process convergence

Theorem (Davis & Hsing `95, Davis & Mikosch `97). Let $\{\mathbf{X}_t\}$ be a stationary sequence of random m -vectors. Suppose

(i) finite dimensional distributions are jointly regularly varying (let $(\theta_{-k}, \dots, \theta_k)$ be the vector in $\mathbf{S}^{(2k+1)m-1}$ in the definition).

(ii) mixing condition $A(a_n)$ or strong mixing.

(iii) $\limsup_{k \rightarrow \infty} \liminf_{n \rightarrow \infty} P(\bigvee_{k \leq |t| \leq r_n} |\mathbf{X}_t| > a_n y \mid |\mathbf{X}_0| > a_n y) = 0$.

Then

$$\gamma = \lim_{k \rightarrow \infty} E(|\theta_0^{(k)}|^\alpha - \bigvee_{j=1}^k |\theta_j^{(k)}|) / E|\theta_0^{(k)}|^\alpha \quad (\text{extremal index})$$

exists. If $\gamma > 0$, then

$$N_n := \sum_{t=1}^n \varepsilon_{\mathbf{X}_t/a_n} \xrightarrow{d} N := \sum_{i=1}^{\infty} \sum_{j=1}^{\infty} \varepsilon_{P_i Q_{ij}},$$

Point process convergence(cont)

- (P_j) are points of a Poisson process on $(0, \infty)$ with intensity function $v(dy) = \gamma \alpha y^{-\alpha-1} dy$.
- $\sum_{j=1}^{\infty} \varepsilon_{Q_{ij}}$, $i \geq 1$, are iid point process with distribution Q , and Q is the weak limit of

$$\lim_{k \rightarrow \infty} E(|\theta_0^{(k)}|^\alpha - \bigvee_{j=1}^k |\theta_j^{(k)}|)_+ I.(\sum_{|t| \leq k} \varepsilon_{\theta_t^{(k)}}) / E(|\theta_0^{(k)}|^\alpha - \bigvee_{j=1}^k |\theta_j^{(k)}|)_+$$

Remarks:

1. GARCH and SV processes satisfy the conditions of the theorem.
2. Limit distribution for sample extremes and sample ACF follows from this theorem.

Extremes for GARCH and SV processes

Setup

- $X_t = \sigma_t Z_t$, $\{Z_t\} \sim \text{IID}(0,1)$
- X_t is RV (α)
- Choose $\{b_n\}$ s.t. $nP(X_t > b_n) \rightarrow 1$

Then

$$P^n(b_n^{-1} X_1 \leq x) \rightarrow \exp\{-x^{-\alpha}\}.$$

Then, with $M_n = \max\{X_1, \dots, X_n\}$,

(i) GARCH:

$$P(b_n^{-1} M_n \leq x) \rightarrow \exp\{-\gamma x^{-\alpha}\},$$

γ is extremal index ($0 < \gamma < 1$).

(ii) SV model:

$$P(b_n^{-1} M_n \leq x) \rightarrow \exp\{-x^{-\alpha}\},$$

extremal index $\gamma = 1$ no clustering.

Extremes for GARCH and SV processes (cont)

(i) GARCH: $P(b_n^{-1}M_n \leq x) \rightarrow \exp\{-\gamma x^{-\alpha}\}$

(ii) SV model: $P(b_n^{-1}M_n \leq x) \rightarrow \exp\{-x^{-\alpha}\}$

Remarks about extremal index.

(i) $\gamma < 1$ implies clustering of exceedances

(ii) Numerical example. Suppose c is a threshold such that

$$P^n(b_n^{-1}X_1 \leq c) \sim .95$$

Then, if $\gamma = .5$, $P(b_n^{-1}M_n \leq c) \sim (.95)^{.5} = .975$

(iii) $1/\gamma$ is the *mean cluster size* of exceedances.

(iv) Use γ to *discriminate* between GARCH and SV models.

(v) Even for the light-tailed SV model (i.e., $\{Z_t\} \sim \text{IID } N(0,1)$), the *extremal index* is 1 (see Breidt and Davis `98)

Extremes for GARCH and SV processes (cont)

Summary of results for ACF of GARCH(p,q) and SV models

GARCH(p,q)

$\alpha \in (0,2)$:

$$(\hat{\rho}_X(h))_{h=1,\dots,m} \xrightarrow{d} (V_h / V_0)_{h=1,\dots,m},$$

$\alpha \in (2,4)$:

$$(n^{1-2/\alpha} \hat{\rho}_X(h))_{h=1,\dots,m} \xrightarrow{d} \gamma_X^{-1}(0)(V_h)_{h=1,\dots,m}.$$

$\alpha \in (4,\infty)$:

$$(n^{1/2} \hat{\rho}_X(h))_{h=1,\dots,m} \xrightarrow{d} \gamma_X^{-1}(0)(G_h)_{h=1,\dots,m}.$$

Remark: Similar results hold for the sample ACF based on $|X_t|$ and X_t^2 .

Summary of results for ACF of GARCH(p,q) and SV models (cont)

SV Model

$\alpha \in (0, 2)$:

$$(n / \ln n)^{1/\alpha} \hat{\rho}_X(h) \xrightarrow{d} \frac{\|\sigma_1 \sigma_{h+1}\|_\alpha}{\|\sigma_1\|_\alpha^2} \frac{S_h}{S_0}.$$

$\alpha \in (2, \infty)$:

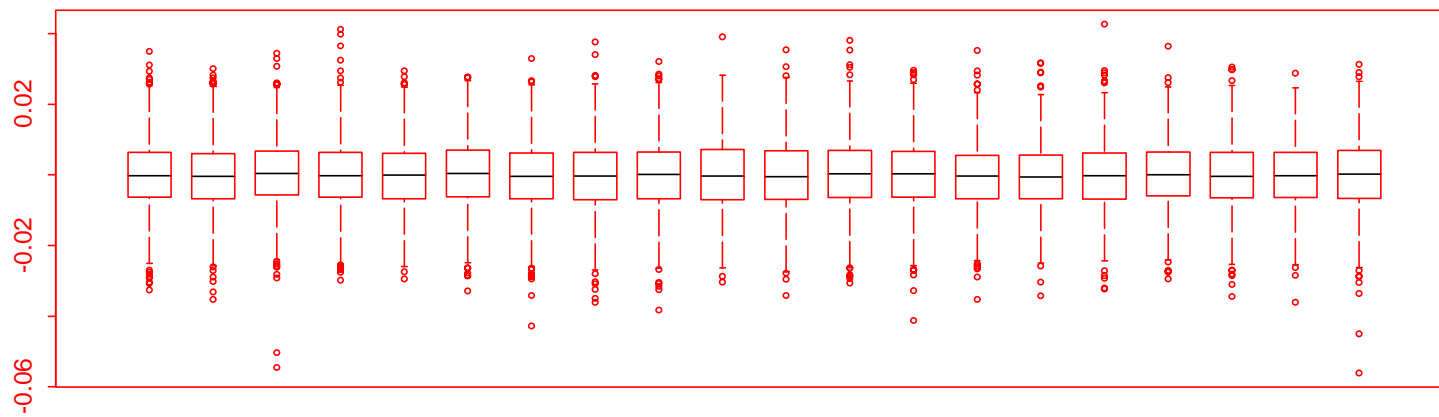

$$\left(n^{1/2} \hat{\rho}_X(h) \right)_{h=1, \dots, m} \xrightarrow{d} \gamma_X^{-1}(0) (G_h)_{h=1, \dots, m}.$$

Sample ACF for GARCH and SV Models (1000 reps)

(a) GARCH(1,1) Model, n=10000

(b) SV Model, n=10000

Sample ACF for Squares of GARCH (1000 reps)

(a) GARCH(1,1) Model, n=10000

b) GARCH(1,1) Model, n=100000

Sample ACF for Squares of SV (1000 reps)

(c) SV Model, n=10000

(d) SV Model, n=100000

Amazon returns May 16, 1997 to June 16, 2004.

Wrap-up

- *Regular variation* is a flexible tool for modeling both *dependence* and *tail heaviness*.
- Useful for establishing *point process convergence* of heavy-tailed time series.
- *Extremal index* $\gamma < 1$ for GARCH and $\gamma = 1$ for SV.

Unresolved issues related to $RV \Leftrightarrow (LC)$

- $\alpha = 2n$?
- there is an example for which $\mathbf{X}_1, \mathbf{X}_2 > 0$, and $(\mathbf{c}, \mathbf{X}_1)$ and $(\mathbf{c}, \mathbf{X}_2)$ have the same limits for all $\mathbf{c} > \mathbf{0}$.
- $\alpha = 2n-1$ and $\mathbf{X} \not\geq 0$ (not true in general).
