(Received 17 May 2014; accepted 5 August 2016; published online 4 November 2016)

We propose herein a new portfolio selection method that switches between two distinct asset allocation strategies. An important component is a carefully designed adaptive switching rule, which is based on a machine learning algorithm. It is shown that using this adaptive switching strategy, the combined wealth of the new approach is a weighted average of that of the successive constant rebalanced portfolio and that of the 1/N portfolio. In particular, it is asymptotically superior to the 1/N portfolio under mild conditions in the long run. Applications to real data show that both the returns and the Sharpe ratios of the proposed binary switch portfolio are the best among several popular competing methods over varying time horizons and stock pools.

1. Introduction

Portfolio selection is an important subject in economics and finance. Among a variety of methods proposed in academia and implemented in practice, Markowitz’s mean–variance portfolio (Markowitz 1952) has become an industry standard and Cover’s Universal Portfolio (CUP) (Cover 1991) is one of the most competitive methods. Both methods have been further extended and improved in the past decades. On the other hand, the naive 1/N rule, which invests equally in each of the N assets, serves as a benchmark for evaluating portfolio performance. Empirical studies support that this naive 1/N rule outperforms many sophisticated portfolios; see, for example, DeMiguel et al. (2009). And it has been shown (Pflug et al. 2012) that the 1/N investment strategy is optimal under high model ambiguity, which means, for a broad class of risk measures, as the uncertainty concerning the probabilistic model increases, the optimal decisions tend to the uniform (1/N) investment strategy.

Markowitz’s mean–variance portfolio, despite its popularity, relies on the assumption about the statistical stationarity of the asset returns as well as the knowledge of the underlying distribution (mean and covariance matrix). In practice, one first estimates the mean and covariance from historical data and then plugs in the resulting estimators. It has been found that Markowitz’s portfolio usually underperforms the naive 1/N rule, both in simulations and in practical implementations (DeMiguel et al. 2009, Tu and Zhou 2011). On the other hand, Cover (1991) showed that his universal portfolio approach has the advantage of not relying on statistical assumptions of the underlying returns and thus can be implemented without parameter estimation. He demonstrated that the CUP is very stable in terms of its performance and the method is universally applicable. Further extensions of the CUP can be found in Jamshidian (1992), Cover (1996), Ordentlich and Cover (1996), Cover and Ordentlich (1996), Kalai and Vempala (2003) and Cross and Barron (2003), among many others. However, it is worth noting that the 1/N method can outperform the CUP in many situations (Belentepe and Wyner 2005).

In the area of online prediction in computer science, the aggregating algorithm (AA) proposed by Vovk (1990) generalizes the weighted majority algorithm (Littlestone and Warmuth 1989) to a much wider class of outcome and action spaces. Vovk and Watkins (1998) applied the AA to portfolio selection. That application can be shown (see section 2) to result in a generalization of the CUP that includes an extra learning rate parameter $\eta$, with the CUP being just a special case with $\eta = 1$. Ignoring the cases with $\eta > 1$, they focused on the cases with $\eta \leq 1$ and obtained a bound on the extra loss, as compared with the best constant rebalanced portfolio (BCRP) (Belentepe and Wyner 2005). Furthermore, Gaivoronski and

*Corresponding author. Email: yangfeng@stat.columbia.edu
Stella (2000) proposed what they called the successive constant rebalanced portfolio (SCRP) method, which is a typical follow-the-leader rule. We note that the AA approximates the SCRP when the learning rate \( \eta \) is large (approaches infinity).

In summary, the AA method contains, as special cases, the 1/N, the CUP and the SCRP with \( \eta \) being equal to 0, 1 and \( +\infty \), respectively.

In this paper, we propose a method called binary switch portfolio (BSP). We first investigate how to adaptively make use of the AA with different values of \( \eta \). We found that switching between the 1/N rule, which is the most conservative constant rebalanced portfolio (CRP), and the SCRP, which is the most aggressive one, provides a simple and approximately optimal investment strategy. A key ingredient in the BSP is the determination of when to switch between the two opposing strategies. Our approach is to apply machine learning techniques to develop a stable switching mechanism. Applications of such machine learning techniques to the description of market regimes and prediction of future returns have given rise to a broad interest; Huang et al. (2005), Qian and Rasheed (2006) and Patel et al. (2015).

Because the SCRP adopts the follow-the-leader rule and therefore can be viewed as momentum-based strategy, while the 1/N rule seeks to increase (decrease) the holdings of those stocks that perform relatively worse (better) than the remaining ones and therefore can be viewed as mean reversion-oriented, the BSP may be interpreted as an investment strategy that alternates between the momentum and mean reverting trading strategies. The intuition for the existence of separate blocks of securities and time ranges in which either a momentum-based strategy or a mean reversion-based one performs better can also be found in Hwang and Rubensam (2015). We provide here further evidence that such blocks not only exist, but also can be identified via machine learning techniques.

This paper provides theoretical justification as well as empirical evidence for the proposed BSP strategy. It first applies the BSP to a data-set that contains 59 stocks from the Hong Kong Stock Exchange from 2008 to 2013. For comparison with existing methods, two additional data-sets, one containing the stocks from the New York Stock Exchange from 1962 to 1984 (Cover 1991), and the other containing the Fama–French 30 industries portfolios (Fama and French 1997), are also analysed. The results show that the BSP significantly outperforms the AA with a fixed learning rate, including the 1/N rule, the CUP and the SCRP, under various time horizons.

The rest of the paper is organized as follows. Section 2 provides a technical background by reviewing the AA approach and establishing a bound on the extra loss of the AA as compared with the BCRP under any fixed learning rate. In section 3, the BSP is introduced and its properties studied. The BSP is applied to several data-sets in section 4 where comparisons with other methods are also given. Some concluding remarks are given in section 5. All the regularity conditions and technical proofs are relegated to Appendices 1 and 2.

2. The AA approach

2.1. Commonly used portfolios

We are concerned with a market containing \( p \) stocks in which discrete time points \( t_0 < t_1 < \cdots < t_n < \cdots \) are under consideration. Let \( s_{n,j} \) be the price of the \( j \)th stock at time \( t_n \). We assume that there is no dividend or transaction cost and that short selling is not allowed. Define \( x_{n,j} = s_{n,j}/s_{n-1,j} \), the simple gross return (price relative) of stock \( j \) for the \( n \)th time period \((t_{n-1}, t_n)\). Let \( x_n = (x_{n,1}, \ldots , x_{n,p})^T \) be the corresponding vector. Here and in the sequel, \( x^T \) denotes the transpose of a vector \( x \). A portfolio corresponds to a \( p \)-vector \( b = (b_1, \ldots , b_p)^T \), where \( b_j \geq 0 \) if \( j = 1, \ldots , p \) and \( \sum_j b_j = 1 \).

The set of such portfolios is denoted by \( B \). Let \( b_n = (b_{n,1}, b_{n,2}, \ldots , b_{n,p})^T \) be the portfolio used in the \( n \)th time period \((t_{n-1}, t_n)\). Thus, \( b_n = (b_1, b_2, \ldots , b_p) \) can be viewed as an investment strategy (portfolio sequence). Furthermore, let \( W_n \) be the total (cumulative) wealth at time \( t_n \) and assume, for simplicity, \( W_0 = 1 \) (unit initial wealth). Therefore, the cumulative wealth under strategy \( b_n \) is

\[
W_n = W_{n-1} x_n^T b_n. \tag{1}
\]

The portfolio construction has to be non-anticipating, meaning that it cannot use information from future stock prices. Let \( \mathcal{F}_n = \sigma(x_1, \ldots , x_n) \) be the \( \sigma \)-field generated from random variables \( x_1, \ldots , x_n \), representing the information accumulation up to time \( t_n \). Then, \( b_n \in \mathcal{F}_{n-1} \), meaning that \( b_n \) is \( \mathcal{F}_{n-1} \) measurable (adapted to \( \mathcal{F}_{n-1} \)).

A particularly simple class of investment portfolios is the so-called CRP; see Cover (1991). For such portfolios, allocation proportions remain the same over the entire investment horizon, i.e. \( b_1 = b_2 = \cdots = b_n \). A special case is the naive and widely used ‘1/N portfolio’, also known as uniformly weighted portfolio, which takes form \( b_{n,1} = \cdots = b_{n,p} = 1/p \). We shall denote the 1/N portfolio by \( b^{(0)} \), i.e.

\[
b^{(0)} = \left( \frac{1}{p}, \ldots , \frac{1}{p} \right)^T .
\]

In general, for a CRP \( b \), let

\[
W_n(b) = \prod_{i=1}^n x_i^T b
\]

represent the total wealth at \( t_n \). Let

\[
b^*_n = \arg \max_{b \in B} W_n(b).
\]

Since \( W_n(b) \leq W_n(b^*_n) \), it follows that \( b^*_n \) would be the BCRP if \( x_1, \ldots , x_n \) were known in advance. We note that the BCRP is not implementable in practice since the \( x_i \) are not known in advance and it serves only as a benchmark for purpose of comparison.

Cover (1991) proposed what he called the universal portfolio and showed that such a portfolio achieves asymptotically the same growth rate as that of the BCRP. CUP is defined as follows:

\[
b^{(1)}_n = \frac{\int b W_{n-1}(b) \pi(db)}{\int W_{n-1}(b) \pi(db)}, \tag{2}
\]
where $\pi$ is a pre-specified prior distribution on $B$. A commonly used prior, to be denoted here by $\pi_0$, is the uniform distribution on $B$.

The AA was introduced in the context of prediction strategies by Vovk (1990) for general outcome and action spaces. Using the AA, a general class of portfolios has the form

$$b_n^{(q)} = \frac{\int \{b \mid W_{n-1}(b)\}^\pi(n\, db)}{\int \{W_{n-1}(b)\}^\pi(n\, db)},$$

(3)

where $\eta \geq 0$ is a pre-chosen constant. In general, $\eta$ may be viewed as the ‘learning rate’ of the AA: a larger value of $\eta$ implies that among all portfolios, we put more weight on those with better historical performances, and less weight on those with poorer performances. As such, it can be understood as a measure of the momentum level. In particular, the special case of $\eta = 1$ corresponds to the CUP, whereas that of $\eta = 0$ corresponds to the $1/N$ rule when $\pi$ is the uniform distribution.

To compare performances among different portfolios, we need to consider the corresponding cumulative wealths and, in particular, their growth rates. Denote by $W_n^{(q)}$ the cumulative wealth at $t_n$ achieved by the AA with learning rate $\eta$. Cover (1991) compared the log-wealth of the CUP, $log W_n^{(1)}$, with the log-wealth of the BCRP, $log W_n(b_n^*)$, and showed that they are of the same order. Vovk and Watkins (1998) further proved that, when the prior $\pi$ has a finite or countable support,

$$\log W_n^{(q)} \geq \log [W_n(b_n^*)] - (p-1) \log n - O(1),$$

(4)

On the other hand, we know that $\log W_n^{(q)} \leq \log [W_n(b_n^*)]$ by the definition of $b_n^*$. Since $\log W_n^{(q)}$ is of order $n$, it is seen from (4) that as $\eta$ gets larger, the performance of the AA is closer to that of the BCRP, i.e., the bound becomes tighter. However, (4) does not hold for $\eta > 1$. In the next subsection, a systematic study will be conducted for the case with $\eta > 1$.

### 2.2. A general bound for AA

In this subsection, we develop a general inequality that covers all positive values of $\eta$ and also extends (4). First, we need the following regularity conditions.

(A.1) There exists a constant $\delta > 0$, such that

$$\lim_{n} \lambda_{\min}\{\frac{1}{n} \sum_{i=1}^{n} x_i x_i^T\} > \delta,$$

where $\lambda_{\min}(M)$ ($\lambda_{\max}(M)$) of matrix $M$ denotes its minimum (maximum) eigenvalue.

(A.2) There exist $0 < c_1 < c_2$, such that, for $i = 1, 2, \ldots, n$, each element of the vector $x_i$ falls in $[c_1, c_2]$.

(A.3) The density of the prior $\pi$, denoted by $f$, exists and is bounded away from 0, i.e. $\inf f(b) > 0$.

Conditions (A.1) and (A.2) are also assumed in Gaivoronski and Stella (2000). Note that the trace of the nonnegative definite matrix in Condition (A.1), which always dominates its maximum eigenvalue, is always 1. Thus, Condition (A.1) implies that the matrix is well conditioned. Condition (A.2) requires that the values of gross returns are bounded away from 0 and $\infty$, i.e. price fluctuations of stocks cannot be extreme. Condition (A.3) is a technical assumption, which is common for a prior on a compact support.

The following lemma quantifies the difference between the AA and the BCRP in terms of their corresponding asset allocation vector at time $n+1$ and $n$, respectively. Its proof will be provided in appendix 2.

**Lemma 2.1** Suppose Conditions (A.1)–(A.3) are satisfied. Then, for any given constant $\eta_0 > 0$, there exists $N > 0$ such that, for all $n > N$ and $\eta \in [\eta_0, +\infty)$,

$$\|b_{n+1}^{(q)} - b_n^*\| \leq \frac{2 \log n}{\delta n^2}.$$

**Remark 1** From lemma 2.1, for a fixed $\eta$, the asset allocation vector of the AA at time $n+1$ is close to that of the BCRP at time $n$ in $L_2$ norm when the time period is large. On the other hand, for a fixed $n$, the conclusion also holds as the learning rate $\eta \rightarrow \infty$.

From lemma 2.1, we immediately have the following proposition, showing that the SCRP (Gaivoronski and Stella 2000), is the limiting case of the AA with $\eta = \infty$. As a result, we use the notation $b_n^{(\infty)}$ to represent the portfolio of the SCRP.

**Proposition 2.2** Under Conditions (A.1)–(A.3), there exists $N > 0$ such that, for all $n > N$,

$$\lim_{\eta \rightarrow \infty} b_n^{(q)} = b_n^{(\infty)}.$$

Using lemma 2.1, the following theorem provides a lower bound of the cumulative wealth $W_n^{(q)}$ for $\eta \geq \eta_0$, with the proof given in appendix 2.

**Theorem 2.3** Under Conditions (A.1)–(A.3), for any given $\eta_0 > 0$, there exists $N > 0$ such that, for all $n > N$ and $\eta \in [\eta_0, +\infty)$,

$$\log W_n^{(q)} \geq \log [W_n(b_n^*)] - \min \left\{ \frac{2\sqrt{2}c_2 p}{c_1^3 \delta n^2 \log n + 2 c_3^2 \log n}, (p-1) \frac{\log n}{n}, \frac{\log n}{2n}, \frac{\log n}{n^{1/2}}, \frac{\log n}{n^{1/3}}, \frac{\log n}{n^{1/4}}, \frac{\log n}{n^{1/5}} \right\},$$

(5)

where $c_1$ and $c_2$ are those defined in Condition (A.2), and $I_{[\eta \leq 1]} = 1$ if $\eta \leq 1$ and 0 otherwise.

**Remark 2** Theorem 2.3 generalizes the results in Vovk and Watkins (1998) for $\eta \leq 1$, Gaivoronski and Stella (2000) for $\eta \rightarrow \infty$ and extends to the case of $\eta \in (1, +\infty)$.

**Remark 3** When $\eta \rightarrow \infty$, (5) reduces to

$$\log W^{(\infty)} \geq \log [W_n(b_n^*)] - \frac{2 \sqrt{2} c_2 p}{c_1^3 \delta} \log (n-1) \frac{1}{c_3^2},$$

which was proved in Gaivoronski and Stella (2000).

**Remark 4** The AA defines a class of portfolios indexed by the learning rate $\eta$. The naive $1/N$ rule, the CUP and the SCRP correspond to the AA with $\eta = 0$ (when $\pi = \pi_0$), $\eta = 1$ and $\eta = \infty$, respectively. Except for the $1/N$ rule, they have the following asymptotic property,

$$\lim_{n} \frac{1}{n} \left[ \log W_n^{(q)} - \log W_n(b_n^*) \right] = 0,$$

(6)

as $n \rightarrow \infty$.  

**Binary switch portfolio**
3. The switching method

In this section, we first study the behaviour of the oracle learning rate of the AA, and then propose a switching method, whose asymptotic behaviour is delineated.

3.1. Oracle learning rate of the AA

At each time point $t_n$, there exists a learning rate $\eta_n^*$, which maximizes the returns during $[t_{n-1}, t_n)$. $n = 1, 2, \ldots$. Specifically,

$$\eta_n^* = \arg \max_{\eta \in [0, \infty)} y_n(\eta),$$

where $y_n(\eta) = x_\eta^T b_n^{(\eta)}$, $n \geq 2$, and $\eta_1^* = 0$. (7)

We call $\eta_n^*$ the ‘oracle learning rate’ as it leads to the maximum return if one were given the information during $[t_{n-1}, t_n)$, which is unknown at time $t_{n-1}$. As a result, it is desirable to develop a strategy that can approximate this ‘oracle learning rate’.

We recognize that $\eta_n^*$ is not adapted to $\mathcal{F}_{n-1}$, i.e., it is not known before $t_n$. If it were known for $n = 1, 2, \ldots$, then the cumulative wealth $W_n^*$ would then be achieved by the strategy

$$B_n^* = (b_{1}(\eta_1^*), b_{2}(\eta_2^*), \ldots, b_{n}(\eta_n^*))$$

Next we search for the $\eta_n^*$ in $[t_{n-1}, t_n)$, $n = 1, 2, \ldots$, to get the cumulative wealth as close to $W_n^*$ as possible. This $W_n^*$, instead of $W_n(b_n^*)$, is our new benchmark in this section. It is larger than $W_n^*(\eta)$ for any fixed $\eta$. Actually, it turns out that it is far larger than $W_n(b_n^*)$, the benchmark we used in the last section, in our numerical experience.

The following list is a segment of $\eta_n$ in 1974 based on daily return data-set of Arcos Dorados Holdings Inc. and Ashford Hospitality Prime Inc. in 1962–1984; see the data-set of New York Stock Exchange analysed in section 4. We optimize $\eta$ that ranges among $\eta \in A = [0, \eta_1, \eta_1, 2, \ldots, \eta_{100}, \eta_{100}, \eta_{2}, \eta_{2}, \ldots, \eta_{2}, 400])$, where $\eta_{1}, \eta_{2}, \ldots, \eta_{100}$ is a geometric sequence with $\eta_{1,1} = \frac{0.0001, \eta_{100} = 0.9999, \eta_{2,1}, \eta_{2,2}, \ldots, \eta_{2,400}}$. Here, $\eta_n^*$ is calculated as follows. We first evaluate $b_n^{(\eta)}$ using (3) for each $n = 1, 2, \ldots$, and each $\eta$ in set $A$, where the set $A$ is chosen to ensure the search area is dense in both $[0, 1]$ and $[1, C]$, where $C$ is sufficiently large. Then we set $\eta_n^* = \arg \max_{\eta \in A} y_n(\eta)$ where $y_n(\eta)$ is defined in (7). Note that if $\eta_n^* = C$, we set it as $\infty$. The list is

\[\begin{array}{cccccccccccc}
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 6 & 1 & 4 & 0 & 5 & 6 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 6 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\end{array}\]

We observe in (8) that 0 and $\infty$ take a large proportion among all possible $\eta_n^*$, $n = 1, 2, \ldots$. In fact, the rate of $\eta_n^* = 0$ or $\infty$ is 84%.

The following lemma characterizes the derivative $\frac{\partial \log|y_n(\eta)|}{\partial \eta}$, which will be used in Theorem 3.2 to quantify the oracle learning rate $\eta_n^*$ under different scenarios.

LEMMA 3.1 Let $b_n^{(\eta)}$ be a random variable that induces the probability $P_{\eta,n}$ on $B$. Then,

$$\frac{\partial \log|y_n(\eta)|}{\partial \eta} = \text{Cov}_n(x_\eta^T b_n^{(\eta)}, \log W_n(\eta)) / \text{E}_\eta(x_\eta^T b_n^{(\eta)}).$$

where $\text{Cov}_n$ and $\text{E}_n$ are covariance and expectation with respect to $b_n^{(\eta)}$, conditioning on all $x_i$, $i = 1, 2, \ldots$

We note that $b_n^{(\eta)}$ and $b_n^{(\eta_0)}$ are different: the former is Random, while the latter is its expectation, i.e., $b_n^{(\eta_0)} = \text{E}_\eta b_n^{(\eta_0)}$. Using lemma 3.1 we have the following theorem.

THEOREM 3.2 Suppose that the prior $\pi = \pi_0$. (a) In general, we have

$$\eta_n^* = 0, \quad \text{if } \text{Cov}_n(x_\eta^T b_n^{(\eta)}, \log W_n(\eta)) < 0 \text{ for all } \eta \in (0, +\infty);$$

$$\eta_n^* = +\infty, \quad \text{if } \text{Cov}_n(x_\eta^T b_n^{(\eta)}, \log W_n(\eta)) > 0 \text{ for all } \eta \in (0, +\infty).$$

(b) Suppose that Conditions (A.1), (A.2), and (A.4)–(A.6) in appendix A hold. Then, for any constant $\alpha > 1$ and any sequence $\eta_{1,n}$ satisfying

$$\frac{n}{(\log n)^\alpha}, \eta_{1,n} \rightarrow \infty,$$

there exists a constant $N > 0$ such that, for any $n > N$,

$$\eta_n^* \in [0, \eta_{1,n}] \cup (+\infty).$$

In addition, if Condition (A.7) also holds, then

$$\eta_n^* \in [\eta_{2,n}, \eta_{1,n}] \cup [0, +\infty)$$

for all large $n$ provided $\eta_{2,n} \rightarrow 0$.

Remark 5 The above theorem shows us the range of possible values for $\eta_n^*$. Part (a) provides a sufficient condition for $\eta_n^* \in [0, \infty]$ and it follows directly from lemma 3.1. An intuitive explanation is that the covariance term is a measure of agreement between the future returns $x_t^T b$ and the historical returns $\log W_{n-1}(b)$. If the covariance term is always positive, then it indicates that we should choose the SCRP. On the other hand, if the term is always negative, it implies that one may need to choose the more conservative 1/N portfolio. In particular, suppose the prior $\pi(db)$ has a discrete support. For example, suppose $\pi(b_1) + \pi(b_2) = 1$, positive $\pi(b_1)$ and $\pi(b_2)$. Then, we have

$$\text{Cov}_n(x_\eta^T b_n^{(\eta)}, \log W_{n-1}(b_n^{(\eta)}))$$

\[\begin{align*}
&\propto \left[ \int x_\eta^T b \log W_{n-1}(b) W_{n-1}(b) \pi(db) \right] \left[ \int W_{n-1}(b) \pi(db) \right] \\
&- \left[ \int x_\eta^T b W_{n-1}(b) \pi(db) \right] \left[ \int \log W_{n-1}(b) W_{n-1}(b) \pi(db) \right] \\
&\propto \left( x_\eta^T b_1 - x_\eta^T b_2 \right) \left( \log W_{n-1}(b_1) - \log W_{n-1}(b_2) \right).
\end{align*}\]

Remark 6 Part (b) tells us that, under some regularity conditions, $[\eta_{2,n}, \eta_{1,n}] \cup [0, \infty)$ is the area to search for $\eta_n^*$ asymptotically, where $1/n \ll \eta_{2,n} \ll \eta_{1,n} \ll (\log n)^{\alpha}/n$. Besides Conditions (A.1)–(A.3) that are explained following lemma 2.1, (A.4) can be found in lemma 4.1 of Cover (1991). Condition (A.5) imposes a limit on the growth rate of the optimal portfolio and this condition is generally satisfied. To see this, the optimal portfolio is obviously better than the risk-free asset, which has an exponential growth rate (positive interest rate). On the other hand, in the long run, the average log-return of any stock should be bounded from above. As a result, limiting the log-return to an interval is reasonable. Condition (A.6) is a technical condition which should be satisfied in most situations. In addition, it can be relaxed by taking a higher order term in the Taylor series.
expansion in the proof, details of which are omitted. Condition (A.7) assumes that $x_n$, $b_n$, and $\log W_n^{-1}(b)$ are correlated in terms of non-vanishing correlation when $n \to \infty$, as $b$ is random with distribution $\pi(b)$.

It is also seen in (8) that usually there is a momentum for the choice of $\eta_n^*$, or a coherence of the $\eta_n^*$ and its neighbours $\eta_{n-1}^*$ and $\eta_{n+1}^*$. This motivates us to derive a data-driven method of choosing $\eta_n$ to approximate $\eta_n^*$ in the next subsection.

### 3.2. The BSP

From theorem 3.2(b), one only needs to search the area $[0, \infty) \cup \{\eta_{2,n}, \eta_{1,n}\}$ for the optimal $\eta$. Note that if $\eta_{1,n} \to 0$, any fixed learning rate in $(0, \infty)$ will be suboptimal in the long-time horizon. To enhance stability and expedite computation, we propose to restrict our search to only 0 and $\infty$, which we would call a ‘binary switch’ algorithm. Throughout the subsection, we redefine

$$\eta_n^* = \arg \max_{\eta_n \in [0, \infty)} y_n(\eta)$$

and

$$W_n^* = W_n^{-1}T_n b_n(\eta_n^*)$$

for $n = 1, 2, \ldots$.

Define

$$C_1 = \{n \geq 2 \mid \eta_n^* = \eta_{n-1}^*\}$$

and

$$C_2 = \{n \geq 2 \mid \eta_n^* \neq \eta_{n-1}^*\}.$$  

Since $\eta_n^*$ is available at time $t_n$, we will have an accurate estimator of $\eta_n^*$ as long as the unknown sets $C_1$ and $C_2$ can be precisely predicted. Now suppose a random function $\kappa$ is a classifier defined on $\mathbb{N} \setminus \{1\}$ that satisfies

$$\kappa : \mathbb{N} \setminus \{1\} \mapsto \{1, 2\},$$

and $\kappa(n) \in \mathcal{F}_{t_n-1}$, for any $n \in \mathbb{N} \setminus \{1\}$.

Here, the value of $\kappa(n) = i$ indicates that we estimate $n \in C_i$, for $i = 1, 2$. Based on the fact that there is a coherence between $\eta_n^*$ and its neighbours, a binary switch procedure is to be specified in the following. Here, we use $\#A$ to denote the cardinality of the set $A$.

**Definition 3.3** Let

$$\mathcal{E}_n(\kappa) = \#\{k = 3, 4, \ldots, n \mid \kappa(k) = 2, k \in C_1 \text{ or } \kappa(k) = 1, k \in C_2\}/(n-2),$$

which is the empirical classification error up to time $t_n$. Also, let

$$\tilde{\eta}_n = \begin{cases} \eta_{n-1}^* & \text{if } \kappa(n) = 1 \text{ and } \mathcal{E}_{n-1}(\kappa) \leq u; \\
0, & \text{otherwise} \end{cases}$$

where $u$ is a pre-specified positive threshold, and $\eta_n^*$ is defined in (10). We call the AA with learning rate $\tilde{\eta}_n$ BSP. In addition, $\tilde{B}_n = (b_1^{(0)}, b_2^{(0)}, b_3^{(0)}, \ldots, b_n^{(0)})$ is called the binary switch strategy.

**Remark 7** The BSP is a conservative procedure in the sense that it will follow the I/N unless it is confident about the assignments and $\eta_{n-1}^* = \infty$.

**Remark 8** Although risk is not being explicitly considered in the CUP and its extensions, there is a strong connection between CUP and the Markowitz portfolio, which balances the return and risk, as being pointed out in Belentepe and Wyner (2005). In fact, by the Taylor series expansion, when $x = q(p(1)$,

$$E[\log(1 + x)] = E(x) - \frac{1}{2}E[(x - E(x))^2],$$

which can be viewed as a mean-variance rule or the well-known Kelly’s rule (Kelly 1956). Consequently, the risk is also controlled in the CUP and its variants including BSP.

To study the theoretical properties of the BSP, we define the concept of compressed cumulative wealth.

**Definition 3.4** Let $\{G_i, i \geq 1\}$ be a filtration. The corresponding $\mathbb{G}_n$-compressed cumulative wealth achieved by strategies $B_n = (b_1, b_2, \ldots, b_n)$ is defined by

$$\exp \left\{ \sum_{i=1}^{n} E[\log x_i^T b_i | F_{i-1}, G_i] \right\}.$$  

In particular, we will use $W_n^{(0)}(G_i), \tilde{W}_n^{(0)}(G_i)$, and $W_n^{(0)}(G_i)$ to denote the $G_n$-compressed cumulative wealth using strategies $B_n^{(0)}$ (I/N), $B_n$ (BSP), and $B_n$ (oracle), respectively.

**Remark 9** It is obvious that

$$W_n^{(0)} = W_n^0, W_n^{(0)}|F_n = W_n^*.$$  

The compressed cumulative wealth compresses the information of returns by conditional expectation on a filtration smaller than $F_n$.

Define

$$C_{0,0} = \{k = 2, 3, \ldots, n \mid \eta_{k-1}^* = 0, \eta_k^* = 0\}$$

$$C_{\infty,\infty} = \{k = 2, 3, \ldots, n \mid \eta_{k-1}^* = +\infty, \eta_k^* = +\infty\}.$$  

Then, $C_1 = C_{0,0} \cup C_{\infty,\infty}, C_2 = C_{0,\infty} \cup C_{\infty,0}$, and we have the following result for the wealth achieved by the BSP.

**Theorem 3.5** If Conditions (B.1) and (B.2) in appendix A holds, then, as $n \to \infty$,

$$P \left\{ \log \tilde{W}_n^{G_i} / \eta_n^{\#} \geq \frac{G_{\infty,0}}{G_{\infty,\infty} + G_{\infty,0}} \log W_n^{(0)}(G_i) + \frac{\tau_{\infty,\infty}}{\tau_{\infty,\infty} + \tau_{\infty,0}} \log W_n^{G_i} - u(\tau_{\infty,\infty} + \tau_{\infty,0}) \right\} \to 1,$$

where $G_k = \sigma(\eta_1^*, \eta_2^*, \ldots, \eta_k^*)$ and $\mathcal{T}_{ij} = \sum E[\log x_i^T b_i^{(j)} - \log x_i^T b_i^{(j)} | F_{i-1}, G_k]$ for $i = 0, \infty, j = 0, \infty$, and the summation over $k \in C_i$. Moreover, if both Conditions (B.1) and (B.2) hold, then $P \left\{ \tilde{W}_n^{G_i} / \tilde{W}_n^{(0)}(G_i) \to 1 as n \to \infty.$

**Remark 10** Condition (B.1) says the classification error rate is less than $u$, while Condition (B.2) says the bound $u$ should not be too large. Thus, Conditions (B.1) and (B.2) provide an upper bound for the classification error rate of the BSP strategy. If the classification error is 0, then (B.1) and (B.2) hold automatically.

The classification error could be interpreted as a risk measure and Conditions (B.1) and (B.2) indicate the risk should be carefully controlled; see also below on measure of risk. It is certainly desirable not to impose structural assumptions on the returns.
Remark 11 Theorem 3.5 shows that, when the classification error is small, the $G_{\kappa}$-compressed cumulative wealth using the BSP is asymptotically larger than the weighted average of the compressed wealth of the oracle aggregating algorithm, i.e. the AA using the oracle learning rate, and the one using the 1/N portfolio. Under additional assumptions, the BSP is uniformly better than the 1/N in terms of compressed cumulative wealth.

To this end, we recommend using the $K$-nearest neighbour method, which is model free. Specifically, for a given $K$, let
\[
\kappa(n) = \begin{cases} 
1, & \text{if } n > K + 1, \text{and } \#\left[\{n-K,n-K+1,\ldots,n-1\}\cap C_{(i)}\right] > 0.5, \\
2, & \text{else.}
\end{cases}
\]
The description of the BSP algorithm is given as follows:

**Algorithm 1** For a given threshold $u > 0$, $\eta_1 = 0$, $\eta_2 = \infty$, classification rule $\kappa$ that satisfies (12), $n \geq 3$, $x_i, i = 1,2,\ldots,n - 1$,
Step 1 Calculate $b_{i,t}^{(n)}$ according to (3), $i = 1, 2, \ldots, n$;
Step 2 Calculate $\eta^*_n$ according to (10), $i = 1, 2, \ldots, n - 1$, and $C_{(i)} \cap \{2, 3, \ldots, n-1\}$ according to (11), $j = 1, 2$;
Step 3 Calculate $\kappa(n), i = 2, 3, \ldots, n$ and the empirical classification error $\bar{e}_{n-1}(\kappa)$ according to (13);
Step 4 We have the output portfolio at $t_n$,
\[
b_{n,t}^{(\kappa)} = \begin{cases} 
b_{n,t}^{(\kappa-1)}, & \text{if } \kappa(n) = 1 \text{ and } \bar{e}_{n-1}(\kappa) \leq u; \\
b_{n,t}^{(0)}, & \text{otherwise.}
\end{cases}
\]

4. Empirical studies

In this section, we show the empirical performance of the BSP for three data-sets, and compare it with those of the 1/N, the CUP, the SCRIP and other portfolio construction methods. To evaluate the overall performance of all methods, we calculate and compare the ending cumulative wealth and Sharpe ratio using all methods to select portfolios from each combination of two stocks. We use $(i,j) \in \{(i,j) | i \neq j, i,j = 1,2,\ldots,p\}$, to represent the $i$th and $j$th stocks. Note that there are $p(p-1)/2$ different combinations. The corresponding returns at $t_n$ could be denoted by $(x_{n,i},x_{n,j})^T$ for the $(i,j)$ combination. For each method, calculate $b_{n,t}^{(i,j)}$ at $t_n$ as the portfolio for $(x_{n,i},x_{n,j})^T$, where $b_{n,t}^{(i,j)} \in \{b \in B | b_{n,k} = 0, \forall k \notin \{i,j\}\}$. The corresponding cumulative wealth and the empirical Sharpe ratio using combination $(i,j)$ are denoted by
\[
W_{n,t}^{(i,j)} = \frac{\sum_{i=1}^{n} x_{n,i}^T b_{n,t}^{(i,j)}},
S_{n,t}^{(i,j)} = \frac{E_n \left[ \left( x_{n,i}^T b_{n,t}^{(i,j)} \right)^2 \right]^{1/2}}{\sqrt{\text{Var}_n \left[ \left( x_{n,i}^T b_{n,t}^{(i,j)} \right)^2 \right]}}.
\]

where $E_n$ and $\text{Var}_n$ indicate the sample mean and variance.

4.1. Hang seng index data-set

The first data-set includes the daily returns of the 59 constituent stocks of the Hong Kong Hang Seng Index (HSI), from 13 March 2008 to 16 April 2013. For each method, a boxplot or a quantile-probability plot of $\{\log W_n^{(i,j)}, i,j = 1,\ldots,p, i < j\}$ or $\{S_n^{(i,j)}, i,j = 1,\ldots,p, i < j\}$ is used to characterize the overall performance for each method. Figure 1(a) and (b) show boxplots that compare the cumulative log-wealth and Sharpe ratio defined by (14), using four different methods i.e. the AA with $\eta = 0$, $\eta = 1$, $\eta = \infty$ and the BSP.

We find that, in general, the performance of the AA with $\eta = 0$ (1/N portfolio) and the BSP are better than that of the AA with $\eta = 1$ or $\infty$. To further compare AA with $\eta = 0$ and the BSP, the quantile-probability plots are shown in figure 2(a) and (b). We find that, for most of $\alpha \in [0,1]$, the corresponding $\alpha$ quantile of log-wealth and Sharpe ratio of the BSP are above those of the 1/N portfolio; see the exact quantile value and the mean value in table 1, where ‘Log-W’ and ‘SR’ represent the log-wealth and empirical Sharpe ratio, respectively.

We also report the median of the annual Sharpe ratios in table 2 for the AA with $\eta = 0$, 0.05, 0.1, 0.5, 1, $\infty$ and the BSP. Here, results using the 1/N method are considered to be the baseline. We observe that the BSP has the largest annual Sharpe ratio for virtually every year. The results of the AA with other learning rates are omitted as they all underperform the BSP.

Lastly, we study the investment on multiple stocks where the BSP is compared with the buy-the-winner strategy (Jegadeesh and Titman 1993). Following Jegadeesh and Titman (1993), we employ the ‘$J$-month/$K$-month’ trading strategy, denoted by ‘(J, K)’, and buy the 6 stocks with largest average returns (top decile). At the beginning of each month we invest $1/K$ of current wealth on the six winner stocks. From table 3, we see that among different trading strategies, buy-the-winner with 3-month/3-month strategy has the largest average returns for the first four years, but performs poorly in 2012–2013. On the other hand, the BSP performs competitively and is stable throughout all the periods considered. In this sense, the BSP can be a viable investment strategy.

4.2. New York Stock Exchange data-set

The second data-set contains the daily returns of 36 stocks in the New York Stock Exchange for the period of 1962–1984. This data-set was used by Cover (1991), Helmbold et al. (1998) and Gaivoronski and Stella (2000). We compare the resulting using four portfolios, i.e. the AA with $\eta = 0$, 1 and $\infty$ and the BSP. The corresponding boxplot and the quantile-probability plot are rendered in figure 1(c), (d), 2(c) and (d), with values given in table 4. The annual Sharpe ratio values are reported in table 5. From these results, we arrive at the same conclusion as in the previous subsection that the overall performance of the BSP is the best among the four portfolios in terms of both Sharpe ratio and the cumulative log-wealth.

To gain insights, we now use three representative stock pairs to show the working mechanism of the BSP. The first pair Ford and Schlum tends to be a ‘follow-the-leader’ type, since more of its $\eta^*_n$ are $\infty$. The observation can be verified by examining figure 3, which displays the proportion of Ford in the BSP over time. It is also clear that the cumulative wealth of BSP is much larger than that of others. The pair Fischer and Morrison tends to be a ‘half-$1/N$-half-follow-the-leader’ type. Figure 4(b) displays the proportion of Fischer over time using the BSP, which demonstrates that there exist blocks of
time for the same type of portfolios, including the 1/N. See figure 5 for stocks Iroquois and Kinark. Figure 5(b) shows the proportion of Iroquois over time using the BSP, which is a constant 0.5. The BSP coincides with the 1/N in figure 5(a). Thus, we can conclude, at least for this data-set, the BSP is indeed an adaptive portfolio selection method that can pick the ‘optimal’ portfolio in all three very different scenarios.

4.3. Fama–French 30 Industry Classification data-set
The third data-set is the monthly return data-set of Fama–French 30 Industry Classifications (Fama and French 1997), which is available from Kenneth French’s webpage. The time period is from July 1926 to December 2011. From tables 6 and 7 and figures 1(e), (f), 2(e) and (f), we again observe
Figure 2. Quantile plot comparison of the AA with $\eta = 0$ and the BSP in terms of cumulative log-wealth and Sharpe ratio. Panels (a) and (b): Hong Kong HSI; Panels (c) and (d): NYSE; Panels (e) and (f): Fama–French 30 Industry Classification.

similar results that the BSP outperforms the AA with a fixed learning rate \( \eta \) for a range of different \( \eta \) values. Using this data-set, we also compare the BSP with other methods, i.e. the weighted successive constant rebalanced portfolios (WSCR) of Gaiorovsni and Stella (2000), the switching portfolios (SP) of Singer (1997) and the exponential gradient method (EG) of Helmbold et al. (1998). Note that the three methods contain a tuning parameter \( \gamma \). We see clearly from table 8 that the BSP attains the largest annual Sharpe ratios in most cases.

5. Concluding remarks

This paper proposes a new portfolio construction method that switches between two opposing investment strategies: one momentum-based and the other mean reverting-oriented. It is motivated by the intuition that there exist blocks of periods in which either the momentum-based or the mean reverting approach is preferred and that the blocks may be identified via suitable machine learning algorithms. Theoretical justification as well as empirical evidence show the superiority of the new method.

In practice, there may exist related macro- and micro-variables. It would be interesting to see how such variables can be incorporated into the learning algorithms. Furthermore, our analysis here does not take into account transaction costs, which could make the situation considerably more complicated.

References

Appendix 1. Conditions

We introduce several additional conditions that are used to prove the theoretical results.

(A.4) All stocks are strictly active: there exist positive constants $N$ and $c_{6}$, such that for any $n > N$, $b_{n,j} > c_{3}, j = 1, 2, \ldots, p$.

(A.5) There exist positive constants $N, c_{4}$ and $c_{5}$, such that for any $n > N, \log W_{n}(b^{*})/n \in [c_{4}, c_{5}]$.

(A.6) There exist positive constants $N, c_{6}, c_{7}$, such that for any $n > N$,

$$
\sum_{i}^{n} x_{i,n-1}^T \mathbf{1}_{j-1}^T \mathbf{1}_{j}^T \gamma_{n}(p-1)^2/2 > c_{6}
$$

where

$$
\mathbf{1}_{j} = \begin{pmatrix}
(x_{n+1,n-1}, x_{n+1,n+1}, 1) \\
(x_{n+1,n-1}, \ldots, x_{n+1,p})
\end{pmatrix}^T,
$$

$$
\mathbf{1}_{j} = \begin{pmatrix}
(x_{n+1,n-1}, 1) \\
(x_{n+1,n-1}, \ldots, x_{n+1,p})
\end{pmatrix}^T,
$$

$$
\gamma_{n} = \frac{n}{\log W_{n}(b^{*})},
$$

where $x'_{j} = (x_{1,1}, \ldots, x_{n-1,p-1})$ and $x'_{j} = (x_{1,1}, \ldots, x_{n-1,p-1})$.

(A.7) There exist positive constants $N$ and $c_{7}$, such that for any $n > N$,

$$
\frac{1}{n} \left| \int_{B} x_{n}^{T} \log W_{n-1}(b) \, d\pi(b) - \int_{B} \log W_{n-1}(b) \, d\pi(b) \times \int_{B} x_{n}^{T} \, d\pi(b) \right| > c_{7}.
$$

(B.1) $E(k) \leq u$, where

$$
E(k) = \lim_{n \to \infty} \mathbb{P}(n \in C_{1}, k(n) = 2 \text{ or } n \in C_{2}, k(n) = 1)
$$

represents the upper limit of the classification error as $n \to \infty$.

(B.2) $\lim_{n \to \infty} \mathbb{P} \left\{ \frac{\tau_{n,\infty,\infty}}{\tau_{n,\infty,0}} \geq u \right\} = 1$.

Appendix 2. Proofs

Proof of Lemma 2.1 For any $b_{0} > 0$, denote $B_{b_{0}}(b^{*}) = \{b \in B | \|b - b^{*}\| < b_{0}\}$.

Let

$$
\tilde{b}_{n}(b_{0}) = \arg \max_{b \in B_{b_{0}}(b^{*})} W_{n}(b) \quad \text{and} \quad \zeta_{n} = \sqrt{\frac{2p}{(1 - 2\epsilon) c_{n}}},
$$

where $\epsilon$ is an arbitrary constant in $(0, 0.5)$. Note that $B_{b_{0}}(b^{*})$ is the compact complement of $B_{b_{0}}(b^{*})$ within $B$. From theorem 2 and equation (16) in [Gaivoronski and Stella (2000)], we have

$$
\frac{1}{n} \log W_{n}(\tilde{b}_{n}(b_{0})) - \frac{1}{n} \log W_{n}(b^{*})
$$

$$
\leq \frac{1}{2} \log W_{n}(b^{*}) (\tilde{b}_{n}(b_{0}) - b^{*}) - \frac{1}{2} \parallel b^{*} - b_{0} \parallel^{2}_{\rho},
$$

(B.2)

If $b^{*}$ is an inner point of $B$, $\frac{1}{2} \log W_{n}(b^{*}) = 0$. On the other hand, if $b^{*}$ is on the boundary of $B$,

$$
\frac{1}{n} \log W_{n}(b^{*}) (\tilde{b}_{n}(b_{0}) - b^{*})
$$

$$
\leq \frac{1}{2} \parallel b^{*} - b_{0} \parallel_{\rho},
$$

(B.1)

due to the optimality of $b^{*}$. Continue with (B.2), we have

$$
\log W_{n}(\tilde{b}_{n}(b_{0})) - \log W_{n}(b^{*}) \leq -\frac{n}{2} \parallel b^{*} - b_{0} \parallel^{2}_{\rho} \leq -\frac{n\delta c^{2}_{n}}{2}.
$$

Choose $\zeta_{n} = (\delta c^{2}_{n} c_{1}/(2c_{2})^{1/2})$. Then, $\zeta_{n} \to 0$ as $n \to \infty$ by the definition of $\zeta_{n}$ in (B1). For any $b \in B_{b_{0}}(b^{*})$, it follows from the mean value theorem and Cauchy inequality that there exists some $b_{1} \in B$, such that

$$
\log W_{n}(b_{1}) - \log W_{n}(b^{*}) \geq \frac{n}{2} \parallel b^{*} - b_{0} \parallel_{\rho}.
$$

(B3)

Condition (A.2) ensures $\parallel \partial \log W_{n}(b_{1})/\partial b \parallel \leq n c_{2}^{1/2}/c_{1}$. Then

$$
\log W_{n}(b_{1}) - \log W_{n}(b^{*}) \geq -n c_{2}^{1/2}/c_{1},
$$

(B4)

From (B3) and (B4), we have $\zeta_{n} < \zeta_{n}$, and for any $b \in B_{b_{1}}(b^{*})$,

$$
\log W_{n}(b) - \log W_{n}(b_{0}(\zeta_{n})) = \log W_{n}(b) - \log W_{n}(b_{1})
$$

$$
+ \log W_{n}(b_{1}) - \log W_{n}(b_{0}(\zeta_{n})) \geq \frac{n \delta c^{2}_{n}}{2} (1 - \epsilon)/2.
$$

(32)
By some straightforward calculation,
\[
\lim_{n \to \infty} \frac{\int_{B_n} (b_j) \int |W_n(b)|^{\pi} \, db}{\int_{B_n} (b_j) \int |W_n(b)|^{\pi} \, db} = \lim_{n \to \infty} \frac{1}{2^n} \left( \frac{\delta}{\pi} \right)^{\pi} \left( b \cdot \mu \right) \langle b \rangle.
\]
which could be seen as the volume of an approximate cylinder with its base having the same area as the selected compact set $B_n$.

It follows from (776) that, we have
\[
\lim_{n \to \infty} \int_{B_n} (b_j) \int |W_n(b)|^{\pi} \, db = \int_{B_n} (b_j) \int |W_n(b)|^{\pi} \, db.
\]

For the uniform prior $\pi = \pi_0$, we observe
\[
\min_{b^*} \int_{B_n} (b_j) \int |W_n(b)|^{\pi} \, db = \min_{b^*} \int_{B_n} (b_j) \int |W_n(b)|^{\pi} \, db,
\]
which is the same as the volume of an approximate cylinder with its top in the area $B_n$ and with the minimum value achieved at the boundary of $B_n$. That is,
\[
\Delta \leq \frac{1}{\lim_{n \to \infty} \exp (\frac{\delta_1^2}{2} (1 - \epsilon))} = \frac{O((n^{-p/2} \pi n^p) \to 0}{\pi_0/n^p),}
\]
holds uniformly in $\eta$, where $h(\eta) = \frac{\pi}{n^p}/p^{2p-1}$. To understand why, we assume, without loss of generality, $p = 0$.

A general continuous prior $\pi$, let $f(\cdot)$ be the density function of $\pi(\cdot)$. Since the support of the prior is the compact set $B$, there exists a constant $C_2 > 0$ with $\int_{B_n} (b_j) \geq C_2$. Then,
\[
\Delta \leq \frac{\int_{f(b)} \int |W_n(b)|^{\pi} \, db}{\int_{B_n} (b_j) \int |W_n(b)|^{\pi} \, db} \leq \frac{1}{\lim_{n \to \infty} \exp (\frac{\delta_1^2}{2} (1 - \epsilon))}.
\]

It follows from (B6) that, $\Delta = O(n^{-p/2} \pi n^p) \to 0$. Recall the definition of $\eta$ in (3), we have
\[
\frac{\log W_n(b^*_{n+1}) - \log W_n(b^*_n)}{c_1} = \frac{\log W_n(b^*_n) - \log W_n(b^*_n)}{c_1}.
\]

For $a \log \log n$, we will use the same argument to show that the above inequality holds for $i = 0, 1$ and $p$ substituted by $f = 1, 2, \ldots, p - 1$. For a general continuous prior $\pi$, let $f(\cdot)$ be the density function of $\pi(\cdot)$. Since the support of the prior is the compact set $B$, there exists a constant $C_2 > 0$ with $\int_{B_n} (b_j) \geq C_2$. Then,
\[
\Delta \leq \frac{\int_{f(b)} \int |W_n(b)|^{\pi} \, db}{\int_{B_n} (b_j) \int |W_n(b)|^{\pi} \, db} \leq \frac{1}{\lim_{n \to \infty} \exp (\frac{\delta_1^2}{2} (1 - \epsilon))}.
\]

Since the summation of the second term on the right side of the inequality above can be approximated by $\frac{\eta_0^2}{\pi} (\log t/1)^2 dt$ and $\eta_0^2 (\log t/1)^2 dt = 2(n \log n)^2 (1 + o(1)) \to \infty$, it follows that
\[
\eta_0 \geq -\frac{2\sqrt{c_2 \pi}}{\sqrt{\delta} \pi} \sqrt{n \log n} + \frac{2c_2 \pi}{c_1} \log n(1 + o(1)).
\]

Proof of part (b) of the theorem is analogous and is thus omitted.
Proof of Theorem 3.2 We only need to prove part (b). We use the notation \( h(n) \sim g(n) \) to represent that
\[
\lim_{n \to \infty} \frac{h(n)}{g(n)} = 1
\]
for sequences \( h(n) \) and \( g(n) \). Using Taylor expansion at \( b^*_n \) up to the sixth order, we have
\[
\log \left[ x_{n+1} \right] = \log \left[ x_{n+1}^T b^*_n \right] + u_0^T (b - b^*_n)
\]
\[
- \frac{1}{2} (b - b^*_n)^T J_0 (b - b^*_n) + \sum_{j_1, j_2 \in [n]} w_{j_1, j_2} (b_{j_1} - b^*_{j_1}) (b_{j_2} - b^*_{j_2}) (b_{j_1} - b^*_{j_1})
\]
\[\vdots\]
\[
+ \sum_{j_1, \ldots, j_6 \in [n]} \prod_{k=1}^6 (b_{j_k} - b^*_{j_k}) \Delta V_1.
\]
\[
\log[W_n(b)] = \log \left[ W_n(b^*_n) \right] - \frac{n}{2} (b - b^*_n)^T J_1 (b - b^*_n)
\]
\[
+ \sum_{j_1, j_2 \in [n]} w_{j_1, j_2} (b_{j_1} - b^*_{j_1}) (b_{j_2} - b^*_{j_2}) (b_{j_1} - b^*_{j_1})
\]
\[\vdots\]
\[
+ \sum_{j_1, \ldots, j_6 \in [n]} \prod_{k=1}^6 (b_{j_k} - b^*_{j_k}) \Delta V_2.
\]
\[
\log[W_n(b)] = \log \left[ W_n(b^*_n) \right] - \frac{n}{2} (b - b^*_n)^T J_2 (b - b^*_n)
\]
\[
+ \sum_{j_1, j_2 \in [n]} w_{j_1, j_2} (b_{j_1} - b^*_{j_1}) (b_{j_2} - b^*_{j_2}) (b_{j_1} - b^*_{j_1})
\]
\[\vdots\]
\[
+ \sum_{j_1, \ldots, j_6 \in [n]} \prod_{k=1}^6 (b_{j_k} - b^*_{j_k}) \Delta V_3.
\]
where
\[
u_0 = \frac{x_{n+1}}{x_{n+1}^T b^*_n}, J_0 = \frac{x_{n+1} x_{n+1}^T}{(x_{n+1}^T b^*_n)^2}, J_1 = \frac{1}{n} \sum_{i=1}^n \frac{x_i x_i^T}{(x_i^T b^*_n)^2},
\]
and \( J_2 = \gamma^*_n J_1 \) with
\[
\gamma^*_n = \frac{n}{n \log W_n(b^*_n)} + \frac{n}{\log W_n(b^*_n)} \sim \gamma_n = \frac{n}{\log W_n(b^*_n)}
\]
Notice that \( \gamma_n \) is bounded from 0 and \( \infty \) under Condition (A.5).

The rest of the proof is divided into three parts.

(I) In the first part, we will prove that, given any sequence
\[
\lambda_n = \sqrt{\frac{2p}{(1 - 2\delta) \Delta n}}, \quad \eta_n = O(1), \quad (\log n)^\alpha \eta_n = o(\eta_n),
\]
where \( \alpha \in (1, 7) \) is a constant, we have
\[n \to \infty, \quad \lambda_n \sim \eta_n \sim \frac{n}{\log W_n(b^*_n)}
\]

(B8)

and
\[
U_n = \gamma_n \left[ u_0^T J_0^{-1} u_0 + (p - 2) \text{tr}(J_0^{-1} J_0) \right] - \gamma_n^2 (p - 1)^2 / 2
\]
\[
\times (1 + o(1)),
\]
\[\text{where}
\]
\[
A = \frac{\exp(- u_0^T (\frac{b_0}{\sqrt{n}} + \gamma_n J_0 + \frac{b}{\sqrt{n}})^{-1} u_0)}{\exp(- u_0^T (\frac{b_0}{\sqrt{n}} + \gamma_n J_0 + \frac{b}{\sqrt{n}})^{-1} u_0)} - 1,
\]
\[\text{for all } b \in (0, 1).
\]

We prove (B9) first. Let
\[
b' = (b_1, \ldots, b_{p-1})^T, \quad b'^*_n = (b'^*_n, \ldots, b'^*_n) \quad \text{and} \quad b^n = (b_1, \ldots, b_{p-1})^T.
\]
\[\text{Then,}
\]
\[
U_0 = (u_0, 0, u_0, \ldots, u_0, 0)^T, \quad \eta_0 = (\xi_1, \ldots, \xi_{p-1})^T
\]
\[\text{and}
\]
\[
\text{where}
\]
\[
\text{for all } b \in (0, 1).
\]
From Taylor expansion, we have the following expansion.

\[
B = \left( \frac{1}{n} + \eta_n \right)^{0.5} - 1, \quad \text{and} \quad C = \left( \frac{1}{n} + \eta_n \right)^{0.5} - 1.
\]

Note that

\[
\tilde{J}_1 = -\frac{\partial^2 \log W_n(b)}{\partial b' \partial b'} = (I_{p-1} - 1_{p-1})^T,
\]

and from Theorem 2 of Gaivornski and Stella (2000), \( \tilde{J}_1 \) is positive definite and \( \lambda_{\min}(\tilde{J}_1) \geq \delta > 0. \)

From Taylor expansion, we have

\[
\begin{align*}
C &= \left( 1 + \frac{\gamma_n^2}{n \gamma_n^2} \right)^{0.5} - 1 \\
&\approx -\frac{p \gamma_n^2}{2n \gamma_n^2} + \frac{(p-1)(p-3)}{8} \frac{\gamma_n^4}{(n \gamma_n^2)^2} + \frac{1}{(n \gamma_n^2)^2} - 1 \\
B &= \left( 1 - \frac{\gamma_n^2}{2n \gamma_n^2} \right)^{0.5} - 1 \\
&\approx -\frac{p \gamma_n^2}{2n \gamma_n^2} + \frac{(p-1)(p-3)}{8} \frac{\gamma_n^4}{(n \gamma_n^2)^2} + \frac{1}{(n \gamma_n^2)^2} - 1.
\end{align*}
\]

where

\[
D = \oint_{B_n(\gamma_n^{0.5})} \frac{\exp(V_1 + \eta_n V_2 + \eta_n V_3) d\mathbf{b}}{\int_{B_n(\gamma_n^{0.5})} \exp(V_1 + \eta_n V_2 + \eta_n V_3) d\mathbf{b}}.
\]

From Taylor expansion, if \( a = 7 \), or \((\log n)^7/n = o(\eta_n)\), we have

\[
\frac{\exp(O(n \eta_n^{0.5}))}{\exp(O(n \eta_n^{0.5}))} = O\left( \frac{1}{(n \eta_n)^{2.5}} \right) = o\left( \frac{1}{(n \eta_n)^{2.5}} \right).
\]

In addition,

\[
D - 1 \approx \frac{\gamma_n^2}{2n \eta_n^2} \left( \frac{1}{\eta_n} \right)^{0.5} - 1 = O(n \eta_n^{0.5}) = \frac{1}{(n \eta_n)^{2.5}}.
\]

Based on the fact that, for any kind of scalar sequences \( (a_n), (b_n), (c_n), \) and \( (d_n) \),

\[
a_n + c_n \frac{b_n}{d_n} - 1 \approx a_n - 1
\]

holds, as long as \( c_n = o(d_n) \), where \( c_n = o(a_n), d_n = o(\eta_n) \). Then (B8) holds.

If \( a \in (1, 7) \), take the integer

\[
K = \min \left\{ k \in \mathbb{Z} \mid k \geq \frac{6a}{a-1} \right\}.
\]

Using Taylor expansion of each term in (B8) up to the \((K-1)\)th order, we have

\[
\frac{\exp(O(n \eta_n^{K}))}{\exp(O(n \eta_n^{K}))} - 1 = O(n \eta_n^K) = o\left( \frac{1}{n \eta_n^2} \right),
\]

and (B8) can be proved along similar lines. In conclusion both (B8) and (B9) hold.

(II) In this part, we prove the first statement of part (b). Choose any \( \epsilon \in \left( \frac{3}{2p+6}, 0.5 \right) \), and \( \eta_n \) and \( \epsilon_n \) the same as in Part (I).

Next similar to (B3) of Lemma 2.1, using Condition (A.5)

\[
\frac{1}{n} \log W_n(\eta_n^{0.5}) \in [c_4, c_5].
\]

we have

\[
\frac{\int_{B_n(\eta_n^{0.5})} \frac{W_n(b) \log W_n(b) dt}{\int_{B_n(\eta_n^{0.5})} W_n(b) dt}}{\int_{B_n(\eta_n^{0.5})} \frac{W_n(b) \log W_n(b) dt}{\int_{B_n(\eta_n^{0.5})} W_n(b) dt}} = n \left( \frac{1}{n \eta_n^{2.5}} \right).
\]

and

\[
\frac{\int_{B_n(\eta_n^{0.5})} \frac{W_n(b) \log W_n(b) dt}{\int_{B_n(\eta_n^{0.5})} W_n(b) dt}}{\int_{B_n(\eta_n^{0.5})} \frac{W_n(b) \log W_n(b) dt}{\int_{B_n(\eta_n^{0.5})} W_n(b) dt}} = n \left( \frac{1}{n \eta_n^{2.5}} \right).
\]

Then we have,

\[
\frac{\int_{B_n(\eta_n^{0.5})} \frac{W_n(b) \log W_n(b) dt}{\int_{B_n(\eta_n^{0.5})} W_n(b) dt}}{\int_{B_n(\eta_n^{0.5})} \frac{W_n(b) \log W_n(b) dt}{\int_{B_n(\eta_n^{0.5})} W_n(b) dt}} = n \left( \frac{1}{n \eta_n^{2.5}} \right).
\]

Thus, we have (B8). Next, we prove (B9). It follows from the integral mean value theorem that

\[
\int_{B_n(\eta_n^{0.5})} \frac{\left( \frac{b'}{b} \right)^{x_n + 1} W_n^{0.5}(b) \log W_n(b) dt}{\int_{B_n(\eta_n^{0.5})} W_n^{0.5}(b) dt} = \frac{1}{n} \left( \frac{1}{n \eta_n^{2.5}} \right).
\]

Downloaded by [Columbia University Libraries] at 10:13 04 January 2018
Hence,

\[
\begin{align*}
\text{Cov}_{B_{\eta_n}^{(n)}}(x_n^T b_n^{\eta_n-1} \log W_{n-1}(b_n^{\eta_n-1})) \\
\text{Cov}_{B_{\eta_n}^{(n)}}(x_n^T b_n^{\eta_n-1} \log W_{n-1}(b_n^{\eta_n-1})) \\
= E_{B_{\eta_n}^{(n)}}(x_n^T b_n^{\eta_n-1} \log W_{n-1}(b_n^{\eta_n-1})) \\
- E_{B_{\eta_n}^{(n)}}(x_n^T b_n^{\eta_n-1}) E_{B_{\eta_n}^{(n)}}(\log W_{n-1}(b_n^{\eta_n-1})) \\
= \frac{E_{B_{\eta_n}^{(n)}}(x_n^T b_n^{\eta_n-1} \log W_{n-1}(b_n^{\eta_n-1})) - E_{B_{\eta_n}^{(n)}}(x_n^T b_n^{\eta_n-1}) E_{B_{\eta_n}^{(n)}}(\log W_{n-1}(b_n^{\eta_n-1}))}{1 - E_{B_{\eta_n}^{(n)}}(x_n^T b_n^{\eta_n-1} \log W_{n-1}(b_n^{\eta_n-1}))} = 0.
\end{align*}
\]

In the end, there exists \( N > 0 \), for any \( n > N \).

\[
\text{Cov}(x_n^T b_n^{\eta_n-1}, \log W_{n-1}(b_n^{\eta_n-1})) = \text{Cov}_{B_{\eta_n}^{(n)}}(x_n^T b_n^{\eta_n-1}, \log W_{n-1}(b_n^{\eta_n-1})) = \int_{B_{\eta_n}^{(n)}}(b_n^T x_n) W_n^\eta_n(b_n \log W_n(b_n)) db \times \int_{B_{\eta_n}^{(n)}}(b_n^T W_n^\eta_n(b_n \log W_n(b_n)) db))^2 \\
\times \frac{\gamma_n[u_n^T J_n^{-1} u'_n - (p - 2) \text{tr}((J_n^{-1} J_n))] - \gamma_n^2 (p - 1)^2/2}{2n^2 \eta_n^2}, \\
(1 + o(1)),
\]

which keeps its sign uniformly for \( \eta_n \in [\eta_1, \eta_\infty) \). Part (a) of the theorem is proved.

(III) We now prove the second statement of Part (b) when Condition (A.7) holds. Using Taylor expansion, as \( n \eta \rightarrow 0 \),

\[
W_n^\eta_n(b) = \exp \left[ \frac{-1}{n} \log W_n(b(\eta_n)) \right] \sim 1 + \eta_n \log W_n(b).
\]

Asymptotically,

\[
\begin{align*}
\int W_n^\eta_n(b) x_n^T b \sigma_\tau(d\theta) \\
\sim \int x_n^T b \sigma_\tau(d\theta) + \frac{1}{n} \log W_n(b) x_n^T b \sigma_\tau(d\theta) \\
\leq \int x_n^T b \sigma_\tau(d\theta) + \frac{1}{n} \log W_n(b_n) x_n^T b \sigma_\tau(d\theta) \\
\leq \int x_n^T b \sigma_\tau(d\theta) + (n \eta)_\tau \int x_n^T b \sigma_\tau(d\theta).
\end{align*}
\]

Similarly, for \( k = 0, 1 \),

\[
\begin{align*}
\int \log W_n(b) W_n^\eta_n(b) (x_n^T b_\tau)^T \pi(d\theta) \\
\sim \int \log W_n(b)(x_n^T b_\tau)^T \pi(d\theta) + O(n \eta).
\end{align*}
\]

Then,

\[
\begin{align*}
\int \log W_n(b) W_n^\eta_n(b) x_n^T b \sigma_\tau(d\theta) - \int W_n^\eta_n(b) x_n^T b \sigma_\tau(d\theta) \\
\times \int \log W_n(b) W_n^\eta_n(b) \pi(d\theta) \\
= \int \log W_n(b) x_n^T b \sigma_\tau(d\theta) - \int x_n^T b \sigma_\tau(d\theta) \times \int \log W_n(b) \pi(d\theta) + o(1).
\end{align*}
\]

With Condition (A.5), it follows that,

\[
\text{Cov}(x_n^T b_n^{\eta_n-1}, \log W_{n-1}(b_n^{\eta_n-1})) = \text{Cov}(x_n^T b_n^{\eta_n}, \log W_{n-1}(b_n^{\eta_n-1}))(1 + o(1)).
\]

We get the conclusion from \( b_\eta_n = b^{(0)} \) and Condition (A.7). □

**Proof of Theorem 3.5**

Write

\[
E \left[ \log x_i^T b_i^{(\eta_i)} - \log x_i^T b_i^{(0)} | \mathcal{F}_{i-1}, i \in C_0,0 \right] \\
= E \left[ \log x_i^T b_i^{(\eta_i)} - \log x_i^T b_i^{(0)} : \kappa(i) = 1 | \mathcal{F}_{i-1}, i \in C_0,0 \right] \\
\times P(\kappa(i) = 1 | \mathcal{F}_{i-1}, i \in C_0,0) \\
+ E[\log x_i^T b_i^{(\eta_i)} - \log x_i^T b_i^{(0)} : \kappa(i) = 2 | \mathcal{F}_{i-1}, i \in C_0,0] \\
\times P(\kappa(i) = 2 | \mathcal{F}_{i-1}, i \in C_0,0) = 0.
\]

(B11)

and

\[
E[\log x_i^T b_i^{(\eta_i)} - \log x_i^T b_i^{(0)} | \mathcal{F}_{i-1}, i \in C_\infty,\infty] \\
= E[\log x_i^T b_i^{(\eta_i)} - \log x_i^T b_i^{(0)} : \kappa(i) = 1 | \mathcal{F}_{i-1}, i \in C_\infty,\infty] \\
\times P(\kappa(i) = 1 | \mathcal{F}_{i-1}, i \in C_\infty,\infty) \\
+ E[\log x_i^T b_i^{(\eta_i)} - \log x_i^T b_i^{(0)} : \kappa(i) = 2 | \mathcal{F}_{i-1}, i \in C_\infty,\infty] \\
\times P(\kappa(i) = 2 | \mathcal{F}_{i-1}, i \in C_\infty,\infty) \\
\leq u E[\log x_i^T b_i^{(\eta_i)} - \log x_i^T b_i^{(0)} | \mathcal{F}_{i-1}, i \in C_\infty,\infty].
\]

(B12)

Similar to (B11) and (B12),

\[
E \left[ \log x_i^T b_i^{(\eta_i)} - \log x_i^T b_i^{(0)} | \mathcal{F}_{i-1}, i \in C_0,0 \right] \\
= E \left[ \log x_i^T b_i^{(\infty)} - \log x_i^T b_i^{(0)} | \mathcal{F}_{i-1}, i \in C_0,0 \right],
\]

and

\[
E \left[ \log x_i^T b_i^{(\eta_i)} - \log x_i^T b_i^{(0)} | \mathcal{F}_{i-1}, i \in C_\infty,\infty \right] \\
\leq u E \left[ \log x_i^T b_i^{(\infty)} - \log x_i^T b_i^{(0)} | \mathcal{F}_{i-1}, i \in C_\infty,\infty \right].
\]

Then,

\[
\begin{align*}
\log W_{n(\eta_n)-1} - \log W_{n(\eta_n)} \\
= \sum_{i=1}^n E \left[ \log x_i^T b_i^{(\eta_i)} - \log x_i^T b_i^{(0)} | \mathcal{F}_{i-1}, \eta_i \right] \\
\leq u \sum_{i \in C_\infty,\infty} E \left[ \log x_i^T b_i^{(\infty)} - \log x_i^T b_i^{(0)} | \mathcal{F}_{i-1}, \eta_i \right] = \infty \\
+ \sum_{i \in C_\infty,\infty} E \left[ \log x_i^T b_i^{(\infty)} - \log x_i^T b_i^{(0)} | \mathcal{F}_{i-1}, \eta_i \right] = \infty \\
+ \sum_{i \in C_\infty,\infty} E \left[ \log x_i^T b_i^{(\infty)} - \log x_i^T b_i^{(0)} | \mathcal{F}_{i-1}, \eta_i \right] = \infty.
\end{align*}
\]

(B13)
Again, analogous to the derivation of (B11) and (B12), we have
\[
\begin{align*}
&\mathbb{E}\left[\log x_i^T b_i^{(\delta)} - \log x_i^T b_i^{(0)} | F_{i-1}, i \in \mathcal{C}_{1,1}\right] = 0, \ j = 1, 2, \\
&\mathbb{E}\left[\log x_i^T b_i^{(\delta)} - \log x_i^T b_i^{(0)} | F_{i-1}, i \in \mathcal{C}_{\infty,\infty}\right] \geq (1 - u) \\
&\times \mathbb{E}\left[\log x_i^T b_i^{(\infty)} - \log x_i^T b_i^{(0)} | F_{i-1}, i \in \mathcal{C}_{\infty,\infty}\right], \\
&\mathbb{E}\left[\log x_i^T b_i^{(\delta)} - \log x_i^T b_i^{(0)} | F_{i-1}, i \in \mathcal{C}_{\infty,0}\right] \geq -u \\
&\mathbb{E}\left[\log x_i^T b_i^{(0)} - \log x_i^T b_i^{(\infty)} | F_{i-1}, i \in \mathcal{C}_{\infty,0}\right].
\end{align*}
\]

Hence,
\[
\begin{align*}
&\log \mathbb{W}_n^{(\eta^*)n} - \log \mathbb{W}_n^{(0)n} \\
&= \sum_{i=1}^{n} \mathbb{E}\left[\log x_i^T b_i^{(\delta)} - \log x_i^T b_i^{(0)} | F_{i-1}, \eta_i^*\right] \\
&\geq (1 - u) \sum_{i \in \mathcal{C}_{\infty,\infty}} \mathbb{E}\left[\log x_i^T b_i^{(\infty)} - \log x_i^T b_i^{(0)} | F_{i-1}, \eta_i^* = \infty\right] \\
&- u \sum_{i \in \mathcal{C}_{\infty,0}} \mathbb{E}\left[\log x_i^T b_i^{(0)} - \log x_i^T b_i^{(\infty)} | F_{i-1}, \eta_i^* = 0\right] \\
&= \Upsilon_{\infty,\infty} + \Upsilon_{\infty,0} + \Upsilon_{\infty,\infty}.
\end{align*}
\] (B14)

Combining (B13) and (B14) leads to the desired conclusion. \qed
